#### Abstract

One of the fundamental questions in current field theory, related to Grothendieck's conjecture of birational anabelian geometry, is the investigation of the precise relationship between the Galois theory of fields and the structure of the fields themselves. In this paper we initiate the classification of additive properties of multiplicative subgroups of fields containing all squares, using pro-2-Galois groups of nilpotency class at most 2 , and of exponent at most 4 . This work extends some powerful methods and techniques from formally real fields to general fields of characteristic not 2 .

## §1. Introduction

Let $F$ be a field of characteristic not 2 and $T$ be a multiplicative subgroup of $\dot{F}=F \backslash\{0\}$ containing the squares. By the additive structure of $T$, we mean a description of the $T$-cosets forming $T+a T$. The purpose of this article is to relate the additive structure of such a group $T$, to some Galois pro-2-group $H$ associated with $T$. In the case when $T$ is a usual ordering, the group $H$ is a group of order 2. In the general case, $H$ is a pro-2-group of nilpotency class at most 2 , and of exponent at most 4. Therefore the structure of $H$ is relatively simple, and this is one of the attractive features of this investigation.
One of our main motivations is to extend Artin-Schreier theory to this general situation. In classical Artin-Schreier theory as modified by Becker, one studies euclidean closures and their relationship with Galois theory [ArSc1, $\mathrm{ArSc} 2, \mathrm{Be}]$. Recall that such a closure is a maximal 2-extension of an ordered field to which the given ordering extends. (See [Be].)
It came as a surprise to us that for a good number of isomorphism types of groups $H$ as above, we could provide a complete algebraic characterization of the multiplicative subgroups of $\dot{F} / \dot{F}^{2}$ associated with $H$, entirely analogous to the classical algebraic description of orderings of fields. We thus obtain a fascinating direct link between Galois theory and additive properties of multiplicative subgroups of fields.
We obtain in particular a Galois-theoretic characterization of rigidity conditions (Proposition 3.4 and Proposition 3.5) using "small" Galois groups, and a full classification of rigid groups $T$ ( $(7)$. We also know how to make closures (as defined below) with respect to these rigid "orderings" (§8).
In $\S 9$ we refine the notion of $H$-orderings of fields. We show that under natural conditions, we can control the behaviour of the additive structure of these orderings under quadratic extensions. It is worthwhile to point out that each finite Galois 2-extension can be obtained by successive quadratic extensions. Therefore, it is sufficient to investigate quadratic extensions.
We have in $\S 2$ a nice illustration of what a $W$-group can or cannot be. Since the $W$-group of the field $F$, together with its level, determines the Witt ring $W(F)$, it is clear that every result about the $W$-group of $F$ and its subgroups will provide information on $W(F)$.
This fits together with one of the main ideas behind this work (see $\S 10$ ): obtaining new Local-Global Principles for quadratic forms, with respect to these new "orderings." This will be the subject of a subsequent article.

We now enter into more detail, fix some notation, and present a more technical outline of the structure of the paper.

Notation 1.1. All fields in this paper are assumed to be of characteristic not 2 , with any exceptions clearly pointed out. Occasionally we denote a field extension $K / F$ as $F \longrightarrow K$. The compositum of two fields $K$ and $L$ contained in a larger field is denoted as $K L$. Recall that the level of a field $F$ is the smallest natural number $n>0$ such that -1 is a sum of $n$ squares in $F$ or
$\infty$ if no such $n$ exists. Given a field $F$, we denote by $F(\sqrt{\dot{F}})$ the compositum of all quadratic extensions of $F$, and by $F^{(3)}$ the compositum of all quadratic extensions of $F(\sqrt{\dot{F}})$ which are Galois over $F$. (The field $F(\sqrt{\dot{F}})$ was denoted by $F^{(2)}$ in previous papers (e.g. [MiSm2]), and this explains the notation $F^{(3)}$.) The W -group of the field $F$ is then defined as $\mathcal{G}_{F}=\operatorname{Gal}\left(F^{(3)} / F\right)$. This Wgroup is the Galois-theoretic analogue of the Witt ring, in that if two fields have isomorphic Witt rings, then their W-groups are also isomorphic. Conversely, if two fields have isomorphic W-groups, then their Witt rings are also isomorphic, provided that the fields have the same level when the quadratic form $\langle 1,1\rangle$ is universal over one of the fields. (See [MiSp2, Theorem 3.8].)
We denote by $\Phi\left(\mathcal{G}_{F}\right)$ the Frattini subgroup of $\mathcal{G}_{F}$. The Frattini subgroup is by definition the intersection of the maximal proper subgroups $H$ of $\mathcal{G}_{F}$. (This means that $H$ is a maximal subgroup of $\mathcal{G}_{F}$ among the family of all closed subgroups of $\mathcal{G}_{F}$ not equal to $\mathcal{G}_{F}$. It is a basic fact in the theory of pro-2-groups that each such subgroup of $\mathcal{G}_{F}$ is a closed subgroup of $\mathcal{G}_{F}$ of index two.) Notice that $\operatorname{Gal}\left(F^{(3)} / F(\sqrt{\dot{F}})\right)=\Phi\left(\mathcal{G}_{F}\right)$. In the case of a pro-2-group $G$, the Frattini subgroup is exactly the closure of the group generated by squares. Observe that for each closed subgroup $H$ of $\mathcal{G}_{F}$ we have $\Phi(H) \subseteq \Phi\left(\mathcal{G}_{F}\right) \cap H$. We say that a closed subgroup $H \subseteq \mathcal{G}_{F}$ satisfying $\Phi(H)=H \cap \Phi\left(\mathcal{G}_{F}\right)$ is an essential subgroup of $\mathcal{G}_{F}$. Two essential subgroups $H_{1}, H_{2}$ are equivalent if $H_{1} \Phi\left(\mathcal{G}_{F}\right)=H_{2} \Phi\left(\mathcal{G}_{F}\right)$. In general, for a closed subgroup $H$ of $\mathcal{G}_{F}$, we have $H=\mathcal{E} \times \prod_{i}(\mathbb{Z} / 2 \mathbb{Z})_{i}$ where $\mathcal{E}$ is essential: $\Phi(H)=\Phi(\mathcal{E})$ and $\Phi\left(\mathcal{G}_{F}\right) \cap H \cong \Phi(\mathcal{E}) \times \prod_{i}(\mathbb{Z} / 2 \mathbb{Z})_{i}$. The equivalence class of $\mathcal{E}$ is that of $H$, and equivalent essential subgroups are always isomorphic. (See [CrSm, Theorem 2.1]. The proof is carried out in the case when $H$ is finite, and the routine technical details necessary for extending the proof for an infinite $H$ have been omitted.)

We recall that a subset $S=\left\{\sigma_{i}, i \in I\right\}$ of a pro- $p$-group $G$ is called a set of generators of $G$ if $G$ is the smallest closed subgroup containing $S$, and for each open subgroup $U$ of $G$, all but finitely many elements of $S$ are in $U$. It is well-known that each pro-p-group $G$ contains a set of generators. A set of generators $S$ of $G$ is called minimal if no proper subset of $S$ generates $S$. (See [Koc, 4.1].)
We now give the field-theoretic interpretation of the notion of an essential subgroup of $\mathcal{G}_{F}$. Let $H$ be any closed subgroup of $\mathcal{G}_{F}$ and let $L$ be the fixed field of $H$. Let $N$ and $M$ be the fixed fields of $\Phi(H)$ and $\Phi\left(\mathcal{G}_{F}\right) \cap H$ respectively. Because $\Phi(H) \subseteq \Phi\left(\mathcal{G}_{F}\right) \cap H$, we see that $M \subseteq N$ and equality holds for one of the inclusions if it holds for the other. Finally observe that $M$ is the compositum of $F(\sqrt{\dot{F}})$ and $L$, and that $N$ is the compositum of all quadratic extensions of $L$ contained in $F^{(3)}$. Summarizing the discussion above we obtain:
Proposition 1.2. Let $H$ be a closed subgroup of $\mathcal{G}_{F}$ and $L$ be the fixed field of $H$. Then $H$ is an essential subgroup of $\mathcal{G}_{F}$ if and only if the maximal multiquadratic extension of $L$ contained in $F^{(3)}$ is equal to the compositum of $L$ and $F(\sqrt{\dot{F}})$.

Kummer theory and Burnside's Basis Theorem allow us to prove the following:
Proposition 1.3. For $H$ a closed subgroup of $\mathcal{G}_{F}$, the assignment

$$
H \mapsto u(H)=P_{H}:=\left\{a \in \dot{F} \mid(\sqrt{a})^{\sigma}=\sqrt{a}, \quad \forall \sigma \in H\right\}
$$

induces a 1-1 correspondence between equivalence classes of essential subgroups of $\mathcal{G}_{F}$ and multiplicative subgroups of $\dot{F} / \dot{F}^{2}$.
Proof. Recall from Kummer theory that $\operatorname{Gal}(F(\sqrt{\dot{F}}) / F)$ is the Pontrjagin dual of the discrete group $\dot{F} / \dot{F}^{2}$ under the pairing $(g,[f])=g(\sqrt{f}) / \sqrt{f}$ of $\operatorname{Gal}(F(\sqrt{\dot{F}}) / F)$ with $\dot{F} / \dot{F}^{2}$, with values in $\mathbb{Z} / 2 \mathbb{Z} \cong\{ \pm 1\}$. (See [ArTa, Chapter 6].)
Assume that $H_{1}$ and $H_{2}$ are two essential subgroups of $\mathcal{G}_{F}$ such that $P_{H_{1}}=$ $P_{H_{2}}=: P$. This means $\frac{H_{1} \Phi\left(\mathcal{G}_{F}\right)}{\Phi\left(\mathcal{G}_{F}\right)}=\frac{H_{2} \Phi\left(\mathcal{G}_{F}\right)}{\Phi\left(\mathcal{G}_{F}\right)}$ because they are both the annihilator of $P$ under the pairing above. (See [Mo, Chapter 5].) Therefore $H_{1} \Phi\left(\mathcal{G}_{F}\right)=H_{2} \Phi\left(\mathcal{G}_{F}\right)$. Hence $u$ is injective on equivalent classes of essential subgroups.
In order to prove that $u$ is surjective, consider any subgroup $P$ of $\dot{F}$ containing $\dot{F}^{2}$. Let $\left\{\left[a_{i}\right], i \in I\right\} \subset \dot{F} / P$ be an $\mathbb{F}_{2}$-basis of $\dot{F} / P$ and $\left\{\bar{\sigma}_{i}, i \in I\right\}$ be elements of $\mathcal{G}_{F} / \Phi\left(\mathcal{G}_{F}\right)$ such that $\bar{\sigma}_{i}\left(\sqrt{a_{i}}\right) / \sqrt{a_{i}}=-1, \bar{\sigma}_{i}\left(\sqrt{a_{j}}\right)=\sqrt{a_{j}}$ for $j \neq i$ and $\bar{\sigma}_{i}(\sqrt{p})=\sqrt{p}$ for all $p \in P$.
From [Koc, 4.4] we see that there exists a subset $S=\left\{\sigma_{i} \mid i \in I\right\}$ of $\mathcal{G}_{F}$ such that the image of each $\sigma_{i}$ in $\mathcal{G}_{F} / \Phi\left(\mathcal{G}_{F}\right)$ is $\bar{\sigma}_{i}$ and for each open subgroup $U$ of $\mathcal{G}_{F}$ all but finitely many elements of $S$ are in $U$. Set $H$ to be the smallest closed subgroup of $\mathcal{G}_{F}$ containing $S$. Because $H / \Phi(H)=\left\langle\bar{\sigma}_{i} \mid i \in I\right\rangle:=$ the smallest closed subgroup of $\mathcal{G}_{F} / \Phi\left(\mathcal{G}_{F}\right)$ generated by $\left\{\bar{\sigma}_{i} \mid i \in I\right\}$, and $P=P_{H}$ we see that $H$ is an essential subgroup of $\mathcal{G}_{F}$ such that $u(H)=P$.

The motivation for this study of essential subgroups grew out of the observation in [MiSp1] that for $H \cong \mathbb{Z} / 2 \mathbb{Z}$, if $P_{H} \neq \dot{F} / \dot{F}^{2}$ (i.e. if $H \cap \Phi\left(\mathcal{G}_{F}\right)=\{1\}$ ), then $P_{H}$ is in fact the positive cone of some ordering on $F$. The reader is referred to [L2] for further details on orderings and connections to quadratic forms. Some convenient references for basic facts on quadratic forms are [L1] and [Sc].
Since the presence or absence of $\mathbb{Z} / 2 \mathbb{Z}$ as an essential subgroup of $\mathcal{G}_{F}$ determines the orderings or lack thereof on $F$, one wonders whether other subgroups of $\mathcal{G}_{F}$ also yield interesting information about $F$. We make the following definition.

## Definition 1.4.

(1) Let $\mathcal{C}$ denote the category of pro-2-groups of exponent at most 4 , for which squares and commutators are central. (Observe that since each commutator is a product of (three) squares, it is sufficient to assume that all squares are central.) All W-groups are in category $\mathcal{C}$. In particular $\Phi\left(\mathcal{G}_{F}\right)$ is in the center of $\mathcal{G}_{F}$, for any $\mathcal{G}_{F}$. See [MiSm2] for further details. Note that $\mathcal{C}$ is a full subcategory of the category of pro-2-groups. This allows us to freely use all of the properties of pro-2-groups.
(2) Let $H$ be a pro-2-group. An embedding $\varphi: H \longrightarrow \mathcal{G}_{F}$ is an essential embedding if $\varphi(H)$ is an essential subgroup of $\mathcal{G}_{F}$. Note that if $H$ embeds in $\mathcal{G}_{F}$, then $H$ has to be in category $\mathcal{C}$.
(3) An $H$-ordering on $F$ is a set $P_{\varphi(H)}$ where $\varphi$ is an essential embedding of $H$ in $\mathcal{G}_{F}$.
(4) Let $(F, T)$ be a field with an $H$-ordering $T$. We say that $(L, S)$ extends $(F, T)$ if $L$ is an extension field of $F$ in the maximal Galois 2-extension $F(2)$ of $F, S$ is a subgroup of $\dot{L}$ containing $\dot{L}^{2}, T=S \cap \dot{F}$, and the induced injection $\dot{F} / T \longrightarrow \dot{L} / S$ is an isomorphism. We also say $(L, S)$ is a $T$-extension of $F$. (We will see in Propositions 4.1 and 4.2 that maximal $T$-extensions always exist, and that a maximal such extension $(L, S)$ in $F(2)$ has $S=\dot{L}^{2}$.) An extension $(L, S)$ of $(F, T)$ is said to be an $H$-extension if $S$ is an $H$-ordering of $L$.
(5) An extension $(L, S)$ of $(F, T)$ is called an $H$-closure if it is a maximal $T$ extension which is also an $H$-extension. Note this implies $S=\dot{L}^{2}$ and $\mathcal{G}_{L} \cong H$. Observe that maximal $H$-extensions $(K, S)$ need not satisfy $S=\dot{K}^{2}$.

We set the following notation: $C_{n}$ denotes the cyclic group of order $n, D$ denotes the dihedral group of order $8, Q$ denotes the quaternion group of order 8.

If $G_{1}$ and $G_{2}$ are in $\mathcal{C}$, we denote by $G_{1} * G_{2}$ the free product (i.e. the coproduct) of the two groups in category $\mathcal{C}$. Then $G_{1}$ and $G_{2}$ are canonically embedded in $G_{1} * G_{2}$ and the latter can be thought of as $\left(G_{1} \times\left[G_{1}, G_{2}\right]\right) \rtimes G_{2}$ with the obvious action of $G_{2}$ on the inner factor. (See [MiSm2].) For example, $D \cong C_{2} * C_{2}$.
Let $a \in \dot{F} \backslash \dot{F}^{2}$. By a $C_{4}^{a}$-extension of a field $F$, we mean a cyclic Galois extension $K$ of $F$ of degree 4 , with $F(\sqrt{a})$ as its unique quadratic intermediate extension. Let $a, b \in \dot{F}$ be linearly independent modulo $\dot{F}^{2}$. By a $D^{a, b}$-extension of $F$ we mean a dihedral Galois extension $L$ of $F$ of degree 8, containing $F(\sqrt{a}, \sqrt{b})$, for which $\operatorname{Gal}(L / F(\sqrt{a b})) \cong C_{4}$. Observe that any $C_{4}$-extension is a $C_{4}^{a}$-extension for an $a \in F$, and that any $D$-extension is a $D^{a, b}$-extension for a suitable $a, b \in \dot{F}$.
The following result is not hard to prove, and is a special case of more general results in [Fr]. (See also [L1, Exercise VII.8].)

Proposition 1.5. There exists a $C_{4}^{a}$-extension of $F$ if and only if $a \in \dot{F} \backslash F^{2}$ and the quaternion algebra $\left(\frac{a, a}{F}\right)$ is split. There exists a $D^{a, b}$-extension of $F$ if and only if $a, b \in \dot{F}$ are independent modulo squares and the quaternion algebra $\left(\frac{a, b}{F}\right)$ is split.

This proposition is one of the main tools we use to link the Galois-theoretic properties of an essential subgroup $H$ of $\mathcal{G}_{F}$ to the algebraic properties of an $H$-ordering. Since we will need to refer to such extensions often in the sequel, we sketch the subfield lattice of a $D^{a, b}$-extension $L / F$.

The paper is organized as follows.
In $\S 2$, we determine centralizers of involutions in W-groups. These results imply in particular that the only abelian groups which can appear as essential nontrivial subgroups of a W -group are $C_{2}$ and $\left(C_{4}\right)^{I}$ where $I$ is some nonempty set. We also determine the possible nonabelian subgroups generated by two elements. In Theorem 2.7 we provide a strong restriction on possible finite subgroups of a $W$-group. Some of these results are important in determining the cohomology rings of $W$-groups.
In $\S 3$ we show how properties of an $H$-ordering $T$, such as stability under addition or rigidity, may be described in a Galois-theoretic way. The definition and first properties of extensions and closures are given in $\S 4$. We illustrate with Proposition 4.4 that even in a very geometric situation, we cannot expect that every $H$-ordering $T$ admits a closure. In Proposition 4.5, that is a corollary of [Cr2, Theorem 5.5], we also point out that this leads to a negative answer to a strong version of the question asked in [Ma]: there are fields $F$ having no field extension $F \longrightarrow K$ with $W_{\text {red }}(K) \cong W(K)$, such that the induced map $W_{\text {red }}(F) \longrightarrow W_{\text {red }}(K)$ is an isomorphism. Later in $\S 8$ we are able to provide a similar example of a field $F$ with a subgroup $T$ of $\dot{F}$ such that the associated Witt ring $W_{T}(F)$ is isomorphic to $W\left(\mathbb{Q}_{p}\right), p \equiv 1(4)$ but again there is no field extension $F \longrightarrow K$ inducing the isomorphism $W_{T}(K) \cong W(K)$. This example is interesting because $|\dot{F} / T|$ is finite. (For details see Example 8.14, Proposition 8.15, and Remark 8.16.)
In $\S 5$ and $\S 6$ we study the case of essential subgroups $H$ generated by 1 or 2 elements, and show that they admit closures.
In $\S 7$ we give a complete Galois-theoretic, as well as an algebraic classification of rigid orderings, and in $\S 8$ we show that they admit closures, provided that in the case of $C(I)$, the associated valuation is not dyadic. (See Theorem 8.15 and Example 8.14.) In Example 6.4 we see that the link between the additive structure of an $H$-ordering and the Galois-theoretic properties of $H$ is not as tight as we might have expected. This leads us to investigate this question more thoroughly in $\S 9$. Actually, with a few natural extra requirements on the

Galois groups we are considering, this can be fixed. We are then able to obtain a perfect identification between the two aspects.
As we have already said, application of this theory to local-global principles for quadratic forms will constitute the core of a subsequent paper. In the conclusion we illustrate by an easy example, what we intend to do in this direction.
The authors would like to acknowledge Professors A. Adem, J.-L. ColliotThélène, T. Craven, B. Jacob, D. Karagueuzian, J. Koenigsmann, T.-Y. Lam, D. Leep and H. W. Lenstra, Jr. for valuable discussions concerning the results in this paper; and also the hospitality of the Mathematical Sciences Research Institute at Berkeley, the Department of Mathematics at the University of California at Berkeley, and the Mathematisches Forschungsinstitut at Oberwolfach, which the authors were privileged to visit during the preparation of this paper. We also wish to thank the anonymous referee for valuable comments and also for suggestions for polishing the exposition.

## §2. Groups not appearing as subgroups of $W$-Groups

In this section we show that no essential subgroup of $\mathcal{G}_{F}$ can have $C_{2}$ as a direct factor (except in the trivial case where the subgroup is $C_{2}$ ), nor can $Q$ appear as a subgroup of $\mathcal{G}_{F}$. These two facts will then be used to show that the four nonabelian groups $C_{2} * C_{2}=D, C_{2} * C_{4}, C_{4} \rtimes C_{4}$ and $C_{4} * C_{4}$, together with the abelian group $C_{4} \times C_{4}$, comprise all of the possible two-generator essential subgroups of W-groups. Thus we have a good picture of the minimal realizable and unrealizable subgroups. We further show that every finite subgroup of a W-group is in fact an "S-group" as defined in [Jo]. (We shall call such groups "split groups" here.) The fact that $Q$ is not a subgroup of $\mathcal{G}_{F}$ is actually a consequence of this last result.
Since we are working in category $\mathcal{C}$ in the presentations of groups by generators and relations, we write only those relations which do not follow from the fact that our groups are in $\mathcal{C}$.

Lemma 2.1. [Mi], [CrSm] The groups $C_{2} \times C_{2}$ and $C_{4} \times C_{2}$ cannot be realized as essential subgroups of $\mathcal{G}_{F}$ for any field $F$.
Proof. Assume $H=\left\langle\sigma, \tau \mid \sigma^{2}=\tau^{2}=[\sigma, \tau]=1\right\rangle \subseteq \mathcal{G}_{F}$ or $H=\langle\sigma, \tau| \sigma^{2}=$ $[\sigma, \tau]=1\rangle$, and assume $\sigma, \tau, \sigma \tau \notin \Phi\left(\mathcal{G}_{F}\right)$. Then from [MiSp1] we know that $P_{\langle\sigma\rangle}$ is a $C_{2}$-ordering which is a usual ordering. In particular $-1 \notin P_{\langle\sigma\rangle}$ and $\sigma(\sqrt{-1})=-\sqrt{-1}$.
Now choose an element $b \in \dot{F} \backslash \dot{F}^{2}$ for which $\sqrt{b}^{\sigma}=\sqrt{b}$ and $\sqrt{b}^{\tau}=-\sqrt{b}$. Such an element $b$ exists since $\sigma, \tau, \sigma \tau \notin \Phi\left(\mathcal{G}_{F}\right)$. Consider the image $\langle\bar{\sigma}, \bar{\tau}\rangle$ of $H$ inside the Galois group $G$ of a $D^{b,-b}$-extension $K$ of $F$. (Because $(\sqrt{-1})^{\sigma}=-\sqrt{-1}$ we see that $-b$ is not a square in $F$, and we can conclude that the elements $b$ and $-b$ are linearly independent when they are considered as elements in $\dot{F} / \dot{F}^{2}$.) The fixed field $K_{\sigma}$ of $\bar{\sigma}$ cannot contain $\sqrt{-b}$, so it must be one of the two subfields of index 2 in $K$ not containing $\sqrt{-b}$. On the other hand, the fixed field $K_{\tau}$ of $\tau$ cannot contain $\sqrt{b}$, so considering the subfield lattice, we see that
$K_{\sigma} \cap K_{\tau}=F$. Then the image of $H$ in $G$ generates $G$, which means $\sigma$ and $\tau$ cannot commute. This is a contradiction, so $H$ cannot exist as an essential subgroup of $\mathcal{G}_{F}$.

From the lemma above we immediately obtain the following result, which is used in [AKMi] to investigate those fields $F$ for which the cohomology ring $H^{*}\left(\mathcal{G}_{F}\right)$ is Cohen-Macaulay.

Corollary 2.2. Let $\sigma$ be any involution in $\mathcal{G}_{F} \backslash \Phi\left(\mathcal{G}_{F}\right)$ and set $E_{\sigma}=\Phi\left(\mathcal{G}_{F}\right) \times$ $\langle\sigma\rangle$. Then the centralizer $Z\left(E_{\sigma}\right)$ of $E_{\sigma}$ in $\mathcal{G}_{F}$ is $E_{\sigma}$ itself.

Proof. If $\tau \in Z\left(E_{\sigma}\right) \backslash E_{\sigma}$ then $[\tau, \sigma]=1$ and $\langle\tau, \sigma\rangle=C_{2} \times C_{2}$ or $C_{4} \times C_{2}$, where $\langle\tau, \sigma\rangle$ is an essential subgroup of $\mathcal{G}_{F}$. From Lemma 2.1, this is a contradiction, and we see $\tau \in E_{\sigma}$ as desired.

Corollary 2.3. No essential subgroup of $\mathcal{G}_{F}$ can have $C_{2}$ as a direct factor (except in the trivial case where the subgroup is $C_{2}$ ).

Proof. Since $\Phi\left(H \times C_{2}\right)=\Phi(H)$, if $H \times C_{2}$ is a subgroup of $\mathcal{G}_{F}$ with $\Phi\left(H \times C_{2}\right)=$ $\left(H \times C_{2}\right) \cap \Phi\left(\mathcal{G}_{F}\right)$, then the $C_{2}$-factor is not in $\Phi\left(\mathcal{G}_{F}\right)$. Take any single element $\sigma \in H \backslash \Phi(H)$. Then $\langle\sigma\rangle \times C_{2} \cong C_{2} \times C_{2}$ or $C_{4} \times C_{2}$, which cannot be an essential subgroup. Therefore neither can $H \times C_{2}$.
Proposition 2.4. The quaternion group $Q$ cannot appear as a subgroup of $\mathcal{G}_{F}$.

Proof. Suppose $Q=\left\langle\sigma, \tau \mid \sigma^{2}=\tau^{2}=[\sigma, \tau]\right\rangle \subseteq \mathcal{G}_{F}$. If $-1 \in F^{2}$, then $F=$ $F^{2}+F^{2}$ and since $\mathcal{G}_{F}$ is not trivial, we have $F \neq F^{2}$. Therefore there exists an element $a \in \dot{F} \backslash F^{2}$ and for any such $a$ we have a $C_{4}^{a}$-extension $L / F$. Since $Q$ does not admit $C_{4}$ as a quotient, the images $\bar{\sigma}, \bar{\tau}$ of $\sigma, \tau$ in $\operatorname{Gal}(L / F)$ have order $\leq 2$ and they fix the only subfield $F(\sqrt{a})$ of codimension 2 in $L$. Then $\sigma, \tau$ act as the identity on the compositum $F(\sqrt{\dot{F}})$ of these fields and hence are in $\Phi(F)$. Since they do not commute, this is impossible and we must have $-1 \notin F^{2}$.
Now suppose $-1 \in P_{\langle\sigma\rangle}$. Since $\sigma \notin \Phi(F)$, there exists $a \in \dot{F}$ such that $a \notin P_{\langle\sigma\rangle}$ and hence $-a \notin P_{\sigma}$. Then $a$ and $-a$ are linearly independent modulo $\dot{F}^{2}$ and there exists a $D^{a,-a}$-extension $L / F$. Again, since $Q$ has no $C_{4}$ quotient, the image $\bar{\sigma}$ of $\sigma$ in $\operatorname{Gal}(L / F)$ has order $\leq 2$ and must fix a codimension 2 subfield of $L$. Therefore $\bar{\sigma}$ must fix $\sqrt{a}$ or $\sqrt{-a}$, and this is a contradiction with $a,-a \notin P_{\langle\sigma\rangle}$. Hence we see that $-1 \notin P_{\langle\sigma\rangle}$.
Because $\sigma$ and $\tau$ are linearly independent modulo $\Phi\left(\mathcal{G}_{F}\right)$, there exists an element $b \in \dot{F} \backslash \dot{F}^{2}$ such that $\sqrt{b}^{\sigma}=\sqrt{b}$ and $\sqrt{b}^{\tau}=-\sqrt{b}$. Then $b$ and $-b$ are linearly independent modulo $\dot{F}^{2}$, and there exists a $D^{b,-b}$-extension $K / F$. Because $D$ is not a homomorphic image of $Q$, the image of $Q$ is a proper subgroup of $\operatorname{Gal}(K / F)$. On the other hand, because both $\sigma$ and $\tau$ act nontrivially and in a different way on $F(\sqrt{b}, \sqrt{-b}) / F$ we see that their images $\bar{\sigma}$ and $\bar{\tau}$ in $\operatorname{Gal}(K / F)$ generate the entire Galois group $\operatorname{Gal}(K / F)$, which is a contradiction!

Theorem 2.5. The only groups generated by two elements which can arise as essential subgroups of $\mathcal{G}_{F}$ are the five groups $C_{2} * C_{2}, C_{2} * C_{4}, C_{4} * C_{4}, C_{4} \times C_{4}$, and $C_{4} \rtimes C_{4}$.

Proof. Let $H$ be generated by $x, y$. We have an exact sequence

$$
1 \rightarrow \Phi(H) \rightarrow H \rightarrow C_{2} \times C_{2} \rightarrow 1
$$

where $\Phi(H) \cong\left(C_{2}\right)^{k}$ is generated by $x^{2}, y^{2},[x, y]$, so $k \leq 3$. Then $|H|=2^{k+2}$, so $|H| \leq 32$, and $|H|=32$ if and only if $|\Phi(H)|=8$, if and only if $H \cong C_{4} * C_{4}$. Otherwise $|H|=8$ or 16 , and there are only a few groups to consider. If $|H|=8$, necessarily $H \cong C_{2} * C_{2}$, as all other groups of order 8 and exponent at most 4 either have $C_{2}$ as a direct factor or are isomorphic to $Q$.
There are fourteen groups of order 16; among these, five are abelian, and by Lemma 2.1 only $C_{4} \times C_{4}$ among these can be an essential subgroup of $\mathcal{G}_{F}$. Among the nine nonabelian groups, two have $C_{2}$ as a direct factor, and four more have exponent 8 . The remaining three are the groups $C_{2} * C_{4}, C_{4} \rtimes C_{4}$, and $D C$, the central product of $D$ and $C_{4}$ amalgamating the unique central subgroup of order 2 in each group. This group, however, has $Q$ as a subgroup (see [LaSm]), so cannot be an essential subgroup of $\mathcal{G}_{F}$.
That the group $Q$ cannot appear as a subgroup of any W -group is a special case of a more general description of the kinds of groups which can appear as essential subgroups of W-groups. All finite subgroups must in fact be "split groups", which we define next. These are the same as "S-groups" as defined in [Jo]. The quaternion group $Q$ is not such a group.

Definition 2.6. Let $G$ be a nontrivial finite group and $X=\left\{x_{1}, x_{2}, \ldots, x_{n}\right\}$ be an ordered minimal set of generators for $G$. We say that $G$ satisfies the split condition with respect to $X$ if $\left\langle x_{1}\right\rangle \cap[G, G]\left\langle x_{2}, \ldots, x_{n}\right\rangle=\{1\}$. The group $G$ is called a split group if it has a minimal generating set with respect to which it satisfies the split condition. We also take the trivial group to be a split group.
We refer to $G$ above as split because if $G$ satisfies the split condition with respect to $X$ then $G$ can be written as a semidirect product $G=\left([G, G]\left\langle x_{2}, \ldots, x_{n}\right\rangle\right) \rtimes$ $\left\langle x_{1}\right\rangle$.

Theorem 2.7. Let $\mathcal{G}_{F}$ be a $W$-group, and let $G$ be any finite subgroup of $\mathcal{G}_{F}$. Then $G$ is a split group.
Proof. Each finite subgroup $H$ of $\mathcal{G}_{F}$ can be written as $H=G \times \prod_{1}^{m} C_{2}$ for some $m \in \mathbb{N} \cup\{0\}$, where $G$ is an essential subgroup of $\mathcal{G}_{F}[\mathrm{CrSm}]$. Thus it is enough to prove the theorem for $G$ a finite essential subgroup of $\mathcal{G}_{F}$.
Then let $G$ be such a group and let $P_{G}$ be the associated $G$-ordering. Let $\dot{F} / P_{G}=\left\langle a_{1} P_{G}, \ldots, a_{n} P_{G}\right\rangle$ so that the cosets $a_{i} P_{G}$ give a minimal generating set for $\dot{F} / P_{G}$. Further set $\left\{\sigma_{1}, \ldots, \sigma_{n}\right\}$ to be a minimal generating set for $G$ such that $\sigma_{i}\left(\sqrt{a_{j}}\right)=(-1)^{\delta_{i j}} \sqrt{a_{j}}$ where $\delta_{i j}$ is the Kronecker delta. (This is possible because $G$ is an essential subgroup of $\mathcal{G}_{F}$, so that a minimal set of
generators for $G$ can be extended to a minimal (topological) generating set of $\mathcal{G}_{F}$.)
Assume first that we can choose the representatives $a_{i}$ in such a way that $a_{1} t_{1}+a_{1} t_{2}=f^{2} \in \dot{F}^{2}$ for some $t_{1}, t_{2} \in P_{G}$. (Note that this is equivalent to saying that $a_{1} \in P_{G}+P_{G}$.) In this instance, there are two cases to consider.
First, suppose that $t_{1}, t_{2}$ are congruent $\bmod \dot{F}^{2}$. Then there exists $g \in \dot{F}$ such that $a_{1} t_{1}+a_{1} t_{1} g^{2}=f^{2}$, and so $a_{1} t_{1} f^{2}=\left(a_{1} t_{1}\right)^{2}+\left(a_{1} t_{1} g\right)^{2}$, and $a_{1} t_{1}$ is a sum of two squares in $F$ which is not itself a square. Thus we have a $C_{4}^{a_{1} t_{1}}$-extension $L$ of $F$. We claim that $G$ satisfies the split condition with respect to $\left\{\sigma_{1}, \ldots, \sigma_{n}\right\}$. Checking this condition is equivalent to showing $\sigma_{1}^{2} \notin[G, G]\left\langle\sigma_{2}, \ldots, \sigma_{n}\right\rangle$. Suppose it is not true. Then we have an identity $\sigma_{1}^{2} \prod_{1 \leq i<j \leq n}\left[\sigma_{i}, \sigma_{j}\right]^{\epsilon_{i j}} \prod_{k=2}^{n} \sigma_{k}^{2 \epsilon_{k}}=1$ in $G$, where $\epsilon_{i j}, \epsilon_{k} \in\{0,1\}$. Restricting to $L$ we see that $\left.\sigma_{1}^{2}\right|_{L}=1$. This cannot be the case as $\sigma_{1}$ does not fix $\sqrt{a_{1} t_{1}}$. Thus in this case $G$ is a split group.
Next suppose that $t_{1} \dot{F}^{2} \neq t_{2} \dot{F}^{2}$. In this case we can find a $D^{a_{1} t_{1}, a_{1} t_{2}}$-extension $L / F$. Assuming again that $G$ does not satisfy the split condition with respect to $\left\{\sigma_{1}, \ldots, \sigma_{n}\right\}$, we again have an identity $\sigma_{1}^{2} \prod_{1 \leq i<j \leq n}\left[\sigma_{i}, \sigma_{j}\right]^{\epsilon_{i j}} \prod_{k=2}^{n} \sigma_{k}^{2 \epsilon_{k}}=1$ in $G$, where $\epsilon_{i j}, \epsilon_{k} \in\{0,1\}$. Since each of the $\sigma_{i}, i=2, \ldots, n$ acts trivially on $F\left(\sqrt{a_{1} t_{1}}, \sqrt{a_{1} t_{2}}\right)$, we see that each $\sigma_{i}, i>1$ is central when restricted to $L$. Thus again $\left.\sigma_{1}^{2}\right|_{L}=1$. But $\left.\sigma_{1}\right|_{L}$ generates $\operatorname{Gal}\left(L / F\left(\sqrt{a_{1} t_{1}} \cdot \sqrt{a_{1} t_{2}}\right)\right) \cong C_{4}$. Hence $G$ is a split group.
Finally, assume that we cannot choose $a_{1} \in P_{G}+P_{G}$. Then necessarily $P_{G}+$ $P_{G} \subseteq P_{G} \cup\{0\}$. If $-1 \in P_{G}$, then $P_{G}=\dot{F}$ and $G=\{1\}$ which is a split group. Otherwise $P_{G}$ is a preordering in $F$, and we may write $P_{G}=\cap_{i=1}^{n} P_{i}$ where each $P_{i}$ is an ordering, and each $P_{i}=\left\{f \in \dot{F} \mid \sqrt{f}^{\sigma_{i}}=\sqrt{f}\right\}$. Then $\left\{\sigma_{1}, \ldots, \sigma_{n}\right\}$ is a minimal generating set for $G$. Furthermore, each $\sigma_{i}^{2}=1$. (See [MiSp1] for details. The definition of a preordering in a field $F$ can be found in [L2, Chapter 1], together with the basic properties of preordered rings.) Thus again we see that $G$ is a split group.

Corollary 2.8. Each nontrivial finite subgroup $G$ of $a W$-group $\mathcal{G}_{F}$ can be obtained inductively from copies of $C_{2}$ and $C_{4}$ by taking semidirect products at each step. Thus we have $G=G_{n} \supseteq G_{n-1} \supseteq \cdots \supseteq G_{1} \supseteq G_{0}$ where $G_{0} \in$ $\left\{C_{2}, C_{4}\right\}$, and $G_{i}=G_{i-1} \rtimes C_{2}$ or $G_{i}=G_{i-1} \rtimes C_{4}$ for each $i=1, \ldots, n$.
Proof. We proceed by induction on the number of generators of $G$. The statement clearly holds for any group $G$ generated by a single element. Let $G$ be any (nontrivial) finite subgroup of the W -group $\mathcal{G}_{F}$. Then we can write $G=H \times \prod_{1}^{m} C_{2}$ where $H$ is essential, and $G$, if not equal to $H$, is clearly built up as described from $H$, where the action in the semidirect product is trivial. We can choose a minimal set of generators $\left\{\sigma_{1}, \ldots, \sigma_{n}\right\}$ for $H$ such that $H$ satisfies the split condition with respect to these generators. Clearly $N:=[H, H]\left\langle\sigma_{2}, \ldots, \sigma_{n}\right\rangle$ is a normal subgroup of $H$, and $H \cong N \rtimes\left\langle\sigma_{1}\right\rangle$, where $\left\langle\sigma_{1}\right\rangle \cong C_{2}$ or $C_{4}$. Since $N \cong\left\langle\sigma_{2}, \ldots \sigma_{n}\right\rangle \times \prod_{1}^{k} C_{2}$ (for some positive integer $k$ ), we finish by induction.

Example 2.9. Consider the W-group $\mathcal{G}_{2}$ of the 2-adic numbers $\mathbb{Q}_{2}$. It has the presentation $\left\langle\sigma, \tau, \rho \mid \sigma^{2}[\tau, \rho]\right\rangle$ in the category $\mathcal{C}$ of groups of exponent at most four with squares and commutators central. (See [MiSp2, Example 4.4].) A basis for $\dot{\mathbb{Q}}_{2} / \dot{\mathbb{Q}}_{2}^{2}$ is given by $\{[-1],[2],[5]\}$, and $\sigma$ may be chosen to fix $\sqrt{2}$ and $\sqrt{5}$ but not $\sqrt{-1}, \tau$ to fix $\sqrt{-1}$ and $\sqrt{5}$ but not $\sqrt{2}$, and $\rho$ to fix $\sqrt{-1}$ and $\sqrt{2}$ but not $\sqrt{5}$. Then $\mathcal{G}_{2}$ can be constructed inductively from copies of $C_{4}$ and $C_{2}$ using semidirect products as follows:

$$
\begin{aligned}
G_{0} & =\langle\rho\rangle \cong C_{4} \\
G_{1} & =G_{0} \times\langle[\sigma, \rho]\rangle \cong G_{0} \times C_{2} \\
G_{2} & =G_{1} \rtimes\langle\sigma\rangle \cong G_{1} \rtimes C_{4} \\
G_{3} & =G_{2} \times\langle[\sigma, \tau]\rangle \cong G_{0} \times C_{2} \\
\mathcal{G}_{2} & =G_{3} \rtimes\langle\tau\rangle \cong G_{3} \rtimes C_{4}
\end{aligned}
$$

Thus $\mathcal{G}_{2} \cong\left\{\left[\left(C_{4} \times C_{2}\right) \rtimes C_{4}\right] \times C_{2}\right\} \rtimes C_{4}$.
Corollary 2.8 is an interesting generalization of the known structure of Wgroups associated with Witt rings of finite elementary type. (See [Ma: pages 122 and 123].) In fact, all W-groups associated with Witt rings of finite elementary type can easily be seen to be built up from cyclic groups of order 2 or 4 , using only semidirect products. First one checks that the groups associated with basic indecomposable groups are such groups. Then the group ring construction for Witt rings corresponds directly to taking a semidirect product with a cyclic group of order 4 , while the direct product construction for Witt rings corresponds to taking a free product of W-groups in the appropriate category. But this in turn just involves taking a direct product with an appropriate number of copies of $C_{2}$ (representing the necessary commutators) and then taking a semidirect product with the generators of one of the initial W-groups. See [MiSm2] for details.
Corollary 2.8 is quite useful for the investigation of cohomology rings of W groups. This is important in light of the recent proof of the Milnor Conjecture by Voevodsky [Vo]. In particular, Voevodsky's result shows that the cohomology rings of absolute Galois groups with $\mathbb{F}_{2}$-coefficients carry no more information about the base field than Milnor's K-theory mod 2. On the other hand, the cohomology rings of W-groups carry substantial additional information. (See [AKMi].)
Using [Jo: Cor, p. 370] and Theorem 2.7 above, we immediately obtain the following.
Corollary 2.10. Let $G$ be any nontrivial finite subgroup of a $W$-group $\mathcal{G}_{F}$. Then the cohomology ring $H^{*}\left(G, \mathbb{F}_{2}\right)$ contains nonnilpotent elements of degree 2, and hence of every even degree.

## §3. Galois groups and additive structures (1)

In this section we give a simple Galois-theoretic characterization of two important additive properties of $H$-orderings: stability under addition and rigidity.

This generalizes the results on rigidity and on the realizability of certain Galois groups obtained in [MiSm1].
For the rest of this paper, unless otherwise mentioned, or if clearly some nonessential subgroups are also considered, subgroups of $\mathcal{G}_{F}$ will always be essential. Nevertheless for the sake of the convenience of the reader we occasionally recall that the considered subgroups are essential. Throughout this paper we write $T+a T=\left\{t_{1}+a t_{2} \mid t_{1}, t_{2} \in T \cup\{0\}, t_{1}+a t_{2} \neq 0\right\}$, so $T$ and $a T$ are always subsets of $T+a T$, and $T+a T \supseteq \dot{F}^{2}$. (Here $T$ is any subgroup of $\dot{F}$ containing all squares in $\dot{F}$.)
Proposition 3.1. Let $H$ be an essential subgroup of $\mathcal{G}_{F}$, and $T$ its associated $H$-ordering. Then $H$ has $C_{4}$ as a quotient if and only if $T+T \neq T$.

Proof. First assume there exists $a \in T+T$ which is not in $T$. Let $K$ be the fixed field of $H$ in $F^{(3)}$. We construct a $C_{4}^{a}$-extension $F_{1}$ of $F_{0}=F(\sqrt{T})=K \cap F^{(2)}$ inside $F^{(3)}$. Then $L=K F_{1}$ is a $C_{4}^{a}$-extension of $K$ in $F^{(3)}$, showing $H$ has $C_{4}$ as a quotient. We may write $a=t_{1}+t_{2}$, so $a^{2}-a t_{1}=a t_{2}$. Let $y=a-\sqrt{a} \sqrt{t_{1}} \in$ $F_{0}(\sqrt{a})$, so $N_{F_{0}(\sqrt{a}) / F_{0}}(y)=[a] \in \dot{F}_{0} / \dot{F}_{0}^{2}$. Then $F_{1}=F_{0}(\sqrt{a}, \sqrt{y})$ is a $C_{4}^{a}$ extension of $F_{0}$. Since $y y^{\sigma}=y^{2}$ or $a t_{2} \in\left(\dot{F}_{0}(\sqrt{a})\right)^{2}$ for all $\sigma \in \operatorname{Gal}\left(F_{0}(\sqrt{a}) / F\right)$, we see $F_{1}$ is Galois over $F$, and hence is contained in $F^{(3)}$.
Conversely, assume $T+T=T$. If $-1 \in T$, then $T=\dot{F}$ and $H=\{1\}$. If $-1 \notin T$, then $T$ is a preordering, so $T$ is an intersection of orderings, and there is an essential subgroup $H_{1}$ of $\mathcal{G}_{F}$ isomorphic with $H$ and $K \subset \Phi\left(\mathcal{G}_{F}\right)$ such that $H_{1} \times K$ is generated by involutions. This follows from the fact that each preordering is an intersection of $C_{2}$-orderings ([L2, Theorem 1.6]), a characterization of $C_{2}$-orderings in [MiSp1] and Proposition 1.3. Thus $H_{1}$ and consequently $H$ as well, cannot have $C_{4}$ as a quotient.

Remark. If $H$ has a $C_{4}$-quotient, then there exists a $C_{4}^{a}$-extension of $F_{0}$ where we may take $a$ to be in $F$. However, it is not necessarily the case that $a \in T+T$. That is, the quaternion algebra $\left(\frac{a, a}{F(\sqrt{T})}\right)$ is split, so $a$ can be represented as the sum of two squares in $F(\sqrt{T})$, but not necessarily as the sum of two elements in $T$. This can be seen in Example 6.4.
The following definition generalizes the notion of the rigidity of a field, and introduces the notion of the level of $T$. (See [Wa, page 1349].)
Definition 3.2. Let $T$ be a subgroup of $\dot{F} / \dot{F}^{2}$. We say that $T$ has level $s$ if -1 is a sum of $s$ elements of $T$, and not a sum of $s-1$ elements of $T$. We say that this level is infinite if -1 is not such a sum for any natural number $s$. We say that the field $F$ is $T$-rigid, or equivalently that $T$ is rigid, if for every $a \notin T \cup-T$, we have $T+a T \subseteq T \cup a T$.

We have the following easy-to-prove but important property of rigid H orderings:
Proposition 3.3. Let $T$ be a rigid $H$-ordering on $F$. Then
(1) The level of $T$ is 1,2 or infinite.
(2) If the level of $T$ is 2 , then $T+T=T \cup-T$.

Proof. Let $T$ be an $H$-ordering of finite level $s>1$ and let us write $-1=a+a_{s}$ with $a=a_{1}+\ldots+a_{s-1}$ and $a_{i} \in T$ for $i=1, \ldots, s$. If $a \in T \cup-T$ then since $a \notin-T$ we see $a \in T$ and $s$ must be 2 . Thus we may assume $a \notin T \cup-T$. If $T$ is rigid, then $-1=a+a_{s} \in T+a T=T \cup a T$. This is a contradiction, proving (1).

Assume the level of $T$ is 2 . Then $-1 \in T+T$ and $T \cup-T \subseteq T+T$. Suppose there is $a \in(T+T) \backslash(T \cup-T)$ and let us write $a=s+t, s, t \in T$. Then of course $-a \notin T \cup-T$ and we have $-t=s-a \in T+(-a) T=T \cup-a T$ by rigidity. But $-t \notin T$ because the level is 2 , and $-t \notin-a T$ because $a \notin T$. This is again a contradiction, proving (2).
Proposition 3.4. Let $H$ be an essential subgroup of $\mathcal{G}_{F}$, and let $T$ be an $H$-ordering. Assume $-1 \in T$. The following are equivalent.
(1) $F$ is $T$-rigid.
(2) $D$ is not a quotient of $H$.
(3) $H$ is abelian.

Proof. We will show $(2) \Longrightarrow(1) \Longrightarrow(3) \Longrightarrow(2)$. For the first implication, we show the contrapositive. Thus assume that $F$ is not $T$-rigid. Let $K$ be the fixed field of $H$, and let $F_{0}=K \cap F(\sqrt{\dot{F}})=F(\{\sqrt{t}: t \in T\})$. We will construct a $D$-extension $F_{1}$ of $F_{0}$ inside $F^{(3)}$, and linearly disjoint with $K$. Then $L=K F_{1}$ will be a $D$-extension of $K$ in $F^{(3)}$, showing that $H$ has $D$ as a quotient. Since $F$ is not $T$-rigid and $-1 \in T$, there exist $a, b \in \dot{F} \backslash T$ such that $b=t_{1}-a t_{2}$, where $t_{1}, t_{2} \in T$ but $b \notin T \cup a T$. Let $y=\sqrt{t_{1}}+\sqrt{a} \sqrt{t_{2}} \in F_{0}(\sqrt{a})$, and let $F_{1}=F_{0}(\sqrt{a}, \sqrt{b}, \sqrt{y})$. Notice that $y y^{\sigma} \in\left\{ \pm y^{2}, \pm b\right\} \subseteq F_{0}(\sqrt{a}, \sqrt{b})^{2}$ for all $\sigma \in \operatorname{Gal}\left(F_{0}(\sqrt{a}, \sqrt{b}) / F\right)$, so $F_{1} / F$ is Galois, and $F_{1} \subseteq F^{(3)}$. Then the usual argument (see [Sp] or [Ki, Theorem 5]) shows Gal $\left(F_{1} / F_{0}\right) \cong D$. Also $F_{1}$ is linearly disjoint with $K$, as no proper quadratic extension of $F_{0}$ is in $K$.
Now assume $F$ is $T$-rigid. To see that $H$ is abelian, it is sufficient to show that for all $\sigma, \tau \in H$, the restrictions of $\sigma, \tau$ to any $D$-extension $L$ of $F$ commute. (This is because $F^{(3)}$ is the compositum of all quadratic, $C_{4}$ - and $D$-extensions of $F$. (See [MiSp2, Corollary 2.18].) Thus if $\sigma, \tau$ commute on all $D$-extensions, they commute in $\mathcal{G}_{F}$.) Let $D^{a, b}$ be some dihedral quotient of $\mathcal{G}_{F}$, and let $L$ be the corresponding extension of $F$. Denote as $\bar{\sigma}, \bar{\tau}$ the images of $\sigma$ and $\tau$ in $D^{a, b}$ and suppose $[\bar{\sigma}, \bar{\tau}] \neq 1$. Then $\sigma, \tau$ must each move at least one of $\sqrt{a}, \sqrt{b}$, and they cannot both act in the same way on these square roots. That implies $a, b, a b \notin T$. But $\left(\frac{a, b}{F}\right)$ splits, so $b \in F^{2}-a F^{2} \subseteq T-a T=T+a T=T \cup a T$ by (1). Since $b \notin T$, we have $b \in a T$, which contradicts the fact that $a b \notin T$. Thus $[\sigma, \tau]=1$.
The final implication is trivial.
It is worth observing that if $4 \leq|\dot{F} / T|$ and if $H$ is abelian then $-1 \in T$. Indeed if $4 \leq|\dot{F} / T|$ and $-1 \notin T$, there exists $[a] \in \dot{F} / T$ such that $[a],[-a]$ are linearly independent in $\dot{F} / T$. Then there exist elements $\sigma, \tau \in H$ such that
their restrictions to $F(\sqrt{a}, \sqrt{-a})$ generate $\operatorname{Gal}(F(\sqrt{a}, \sqrt{-a})) / F$. Subsequently images of $\sigma, \tau$ generate $\operatorname{Gal}(L / F)$ for any $D^{a,-a}$ extension $L / F$. Thus $H$ is not abelian. In the next proposition we freely use the fact that if $H_{1}$ is an essential part of the subgroup $H_{0}$ of $\mathcal{G}_{F}$, then $H_{1}$ admits a quotient $D$ if and only if $H_{0}$ admits a quotient $D$.
Proposition 3.5. Let $H$ be an essential subgroup of $\mathcal{G}_{F}$, and let $T$ be an $H-$ ordering. Assume $-1 \notin T$. Let $K$ be the fixed field of $H$, and let $H_{0}$ be the subgroup of $H$ which is the Galois group of $F^{(3)} / K(\sqrt{-1})$. The following are equivalent.
(1) $F$ is $(T \cup-T)$-rigid.
(2) $D$ is not a quotient of $H_{0}$.
(3) $H_{0}$ is abelian.
(4) Every $D$-extension of $K$ in $F^{(3)}$ contains $K(\sqrt{-1})$.

Proof. Let $S=T \cup-T$ and let $H_{1}$ be an essential part of $H_{0}$. Then $S$ is an $H_{1}$-ordering, and the equivalence of the first three statements follows from the preceding proposition. If there exists a $D$-extension $L$ of $K$ not containing $K(\sqrt{-1})$, then $L(\sqrt{-1})$ will be a $D$-extension of $K(\sqrt{-1})$, and $H_{0}$ will have $D$ as a quotient. This shows $(2) \Longrightarrow(4)$. In order to show that $(4) \Longrightarrow(3)$, assume there exist $\sigma, \tau \in H_{0}$ which do not commute. Then there exists some $D^{a, b}$-extension $M$ of $F$ such that $\operatorname{Gal}(M / F)=\langle\bar{\sigma}, \bar{\tau}\rangle$, where we denote by $\bar{\sigma}$ and $\bar{\tau}$ the images of $\sigma$ and $\tau$ in $\operatorname{Gal}(M / F)$. Then $\sigma$ and $\tau$ each move at least one of $\sqrt{a}, \sqrt{b}$ and cannot act in the same way on each. Thus $a, b, a b \notin S$. This gives a $D$-extension $M K$ of $K$, which does not contain $\sqrt{-1}$.

## §4. Maximal extensions, Closures and examples

Given any $C_{2}$-ordering $P$ on a field $F$, one can find a real closure $L$ of $F$ with respect to that ordering, inside a fixed algebraic closure $\bar{F}$. This means $L$ is real closed and $P=\dot{L}^{2} \cap F$, and then $\operatorname{Gal}(\bar{F} / L) \cong C_{2}$. Notice that for our purposes nothing is lost by considering a real closure of $F$ inside a euclidean closure $F(2)$ rather than inside the algebraic closure $\bar{F}$. (See [Be].) We then obtain a $C_{2^{-}}$ closure $\left(L, \dot{L}^{2}\right)$ of $(F, P)$, and this observation actually motivated the definition of $H$-closure given in Definition 1.4. The following two propositions show that for any subgroup $T$ of $\dot{F}$, containing $\dot{F}^{2}$, maximal $T$-extensions always exist and have a nice property.
Proposition 4.1. Let $T$ be a subgroup of $\dot{F} / \dot{F}^{2}$. Then $(F, T)$ possesses a maximal $T$-extension.
Proof. Let $\mathcal{S}$ be the set of $T$-extensions $(L, S)$ of $(F, T)$ inside $F(2)$, and let us order $\mathcal{S}$ by $\left(L_{1}, S_{1}\right) \leq\left(L_{2}, S_{2}\right)$ if $L_{1} \subset L_{2}$ and $S_{2} \cap L_{1}=S_{1}$. Then $\mathcal{S}$ is nonempty, since $(F, T) \in \mathcal{S}$. Now consider a totally ordered family $\left(F_{j}, T_{j}\right)$ in $\mathcal{S}$. Let $K=\cup F_{j}, S=\cup T_{j}$. Then $(K, S)$ is an upper bound for the family $\left(F_{j}, T_{j}\right)$ in $\mathcal{S}$. Then by Zorn's Lemma $\mathcal{S}$ contains a maximal element, which is a maximal $T$-extension of $(F, T)$.

Proposition 4.2. Let $(K, S)$ be a maximal $T$-extension of $(F, T)$. Then $S=$ $\dot{K}^{2}$.

Proof. Assume $S \neq \dot{K}^{2}$ and choose $c \in S \backslash \dot{K}^{2}$. Let $L=K(\sqrt{c})$. Then $\dot{K} / S \cong \dot{K} \dot{L}^{2} / S \dot{L}^{2}$ is an $\mathbb{F}_{2}$-vector subspace and hence a summand of $\dot{L} / S \dot{L}^{2}$. Pick any projection $\varphi$ of $\dot{L} / S \dot{L}^{2}$ onto $\dot{K} \dot{L}^{2} / S \dot{L}^{2}$. Set $S^{\prime}$ as the inverse image of $\operatorname{ker} \varphi$ in $\dot{L}$. Then the natural inclusions $\dot{F} \longrightarrow \dot{K}$ and $\dot{K} \longrightarrow \dot{L}$ induce the isomorphisms $\dot{F} / T \cong \dot{K} / S \cong \dot{L} / S^{\prime}$, contradicting the maximality of $(K, S)$. Thus we conclude that $S=\dot{K}^{2}$.

Corollary 4.3. An $H$-ordered field $(F, T)$ is an $H$-closure if and only if $T=\dot{F}^{2}$.

Proof. If $(F, T)$ is an $H$-closure, then it is also a maximal $T$-extension, and $T=\dot{F}^{2}$ by the preceding proposition. Conversely, suppose $T=\dot{F}^{2}$. Let $L \supset F$ be any proper extension of $F$ in $F(2)$. Then $L$ contains a quadratic extension of $F$, so $\dot{L}^{2} \cap F \supsetneq \dot{F}^{2}$ and $L$ cannot extend $(F, T)$. This shows that $(F, T)$ is its own maximal $T$-extension, and as it is an $H$-ordering, it is an $H$-closure.

Thus, if we want to show the existence of an $H$-closure for an $H$-ordered field $(F, T)$, we have to show that there exists a maximal $T$-extension $\left(K, \dot{K}^{2}\right)$ for an $H$-ordered field, which is itself $H$-ordered, i.e. for which $\mathcal{G}_{K} \cong H$.
The following proposition indicates that even very simple preorderings may have a surprising behaviour in the context of a $T$ - or $H$-extension. The proof of this proposition is no less interesting than the proposition itself, as it relies upon visual geometrical arguments involving topology of the plane.

Proposition 4.4. Let $F=\mathbb{R}(X, Y)$ and let $T$ be the set of nonzero sums of squares in $F$. If $H$ is an essential subgroup of $\mathcal{G}_{F}$ such that $T=P_{H}$, then the $H$-ordered field $(F, T)$ does not admit an $H$-closure.

Proof. Suppose that we are in the situation described in our proposition. Then $H \neq\{1\}$ and by Proposition 3.1 the group $H$ does not admit a $C_{4}$ quotient. Thus again by Proposition 3.1, if $\left(\dot{K}, \dot{K}^{2}\right)$ is an $H$-closure of $(F, T)$, then $\dot{K}^{2}$ is a preordering in $K$. Choose $s \in T \backslash \dot{F}^{2}$, fix an embedding of $L=F(\sqrt{s})=$ $F[Z] /\left(Z^{2}-s\right)$ in $K$ and set $P=L \cap \dot{K}^{2}$. The intermediate extension $(L, P)$ between $(F, T)$ and $\left(K, \dot{K}^{2}\right)$ is a $T$-extension of $(F, T)$ and $P=L \cap \dot{F}^{2}$ is a preordering of $L$.
Call $z$ the class of $Z$ in $L$. For every element $h \in \dot{L}$ there is a $g \in \dot{F}$ such that $g h \in P$. In particular, there is $f \in \dot{F}$ such that $z f \in P$. Call $\hat{P}$ the set of orderings of $L$ that contain $P$, and denote by $N$ the norm of $L$ down to $F$. The embedding $F \longrightarrow L$ induces a map $\pi: X(L) \longrightarrow X(F)$ between the corresponding spaces of orderings, defined by $\alpha \mapsto \alpha \cap F$.
Let us show first that $\pi$ induces an injection from $\hat{P}$ to $X(F)$. Let $\alpha_{1}, \alpha_{2}$ be two orderings of $L$ containing $P$ such that $\alpha=\alpha_{1} \cap F=\alpha_{2} \cap F$. Then the element $f \in F$ introduced above has a given $\operatorname{sign} \epsilon= \pm 1$ at $\alpha$, and thus has this same sign at $\alpha_{1}$ and $\alpha_{2}$. Since $z f \in P \subset \alpha_{1} \cap \alpha_{2}, z$ also has the same sign
at $\alpha_{1}$ and $\alpha_{2}$. But this cannot be, since the product of these signs is the sign of $N(z)=-s$ at $\alpha$, which is negative.
Now, $\pi$ also induces a surjection from $\hat{P}$ onto $X(F)$, and this is a bit deeper. Briefly, it goes as follows. Suppose $\alpha$ is an ordering of $F$ such that none of the extensions $\alpha_{1}, \alpha_{2}$ to $L$ contain $P$. Then we can find $u \in L$ such that $u \in P$ and $-u \in \alpha_{1} \cap \alpha_{2}$. Denote by $D_{E}\left(w_{1}, \ldots, w_{n}\right)$ the set of orderings of a field $E$ containing the given elements $w_{1}, \ldots, w_{n} \in E$. It is an open set for the Harrison topology on $X(E)$. Considering $\alpha_{1}, \alpha_{2}$ as points in $X(L)$ and $\hat{P}$ as a subset of $X(L)$, we may write $\alpha_{1}, \alpha_{2} \in D_{L}(-u)$ and $D_{L}(-u) \cap \hat{P}=\emptyset$. In other words, $D_{L}(-u)$ separate $\left\{\alpha_{1}, \alpha_{2}\right\}$ from $\hat{P}$. Now, one may check easily that there exists an open nonempty set $V$ in $X(F)$ such that $\pi^{-1}(V) \subset D_{L}(-u)$. Due to the fact that $F$ is the function field of an algebraic variety over a real closed field, we know that every open set of $X(F)$, and in particular $V$ contains a nonempty set $D_{F}(v)$ for some $v \in F$. Since $D_{L}(v) \cap \hat{P}=\emptyset,-v$ must be in any ordering containing $P$, and thus must be in $P$. Hence $-V \in T$, and $V$, are in any ordering of $F$. Since $D_{F}(v) \neq \emptyset$, this is a contradiction which proves the surjectivity of $\pi$ on $\hat{P}$.
Since $\pi$ is surjective on $\hat{P}$, we have $\pi\left(D_{L}(w) \cap \hat{P}\right)=D_{F}(w)$ for $w \in F$, and since $z f \in P, \pi\left(D_{L}(w z) \cap \hat{P}\right)=D_{F}(w f)$. Coming back to $h=a+b z \in L$ with $a, b \in$ $F$, it is known (and easy to see) that $D_{L}(h)=D_{L}(N(h), a) \cup D_{L}(-N(h), b z)$. Since $\pi$ is injective on $\hat{P}$, it preserves intersection (and of course unions) and thus $\pi\left(D_{L}(h) \cap \hat{P}\right)=D_{F}(N(h), a) \cup D_{F}(-N(h), b f)$. On the other hand, for $g \in F$ such that $g h \in P$, we have $\pi\left(D_{L}(h) \cap \hat{P}\right)=D_{F}(g)$. What we have proved so far is that for any $h=a+b z \in L, D_{F}(N(h), a) \cup D_{F}(-N(h), b f)$ is a "principal" set $D_{F}(g)$ in $X(F)$.
Let us show that this is impossible in general. Take $s=1+X^{2}$ and $h=$ $Y+c+b z \in L$ with $c, b \in \mathbb{R}, b>0$. Assume that the corresponding set $D_{F}(N(h), Y+c) \cup D_{F}(-N(h), f)$ is the principal set $D_{F}(g)$ for a given squarefree polynomial $g \in F$. (This can always be achieved.) Note that $N(h)=0$ is the equation $(Y+c)^{2}=b^{2}\left(1+X^{2}\right)$ of a hyperbola $\mathcal{H}$ in $\mathbb{R}^{2}$. Set $A:=\{(X, Y) \in$ $\left.\mathbb{R}^{2} \mid N(h)>0, \quad Y+c>0\right\}$ (respectively $B:=\left\{(X, Y) \in \mathbb{R}^{2} \mid N(h)>\right.$ $0, \quad Y+c<0\})$ the open region of the plane above (respectively below) the upper (respectively lower) branch of $\mathcal{H}$. Denote by $\tilde{A}, \tilde{B}$ the subsets defined in $X(F)$ by the same inequalities as for $A, B$. By assumption, we know that $g>0$ on $\tilde{A} \cap X(F)=D_{F}(N(h), Y+c)$ and $g<0$ on $\tilde{B} \cap X(F)=D_{F}(N(h),-(Y+c))$. This implies that $g \geq 0$ on $A$ and $g \leq 0$ on $B$ (see [BCR], §7.6) and that $A$ and $B$ are separated by a branch (i.e. a 1-dimensional irreducible connected component) of $g=0$. Moreover, no branch of $g=0$ can go inside $A \cup B$, or else $g$ would change sign on $A$ or $B$. (This is due to the fact that $g$ is square free, and thus every branch is a sign-changing branch.) Set $C:=\mathbb{R}^{2} \backslash A \cup B$. Then $\tilde{C} \cap X(F)=D_{F}(-N(h))$. Since $D_{F}(g,-N(h))=D_{F}(b f,-N(h))=$ $D_{F}(f,-N(h))$, we know that $f$ and $g$ have the same sign on $C$, up to a 0 dimensional set. Thus $f=0$ must also have a sign-changing branch contained in $C$, and since $f$ may be chosen square free, any branch of $f=0$ having a
nonempty intersection with the interior of $C$ must be contained in $C$.
Suppose this is true at the same time for $h=h_{1}=Y+z$ and $h=h_{2}=Y+4+2 z$. Then
(1) no branch of $f=0$ is allowed to cross a branch of the hyperbolas $\mathcal{H}_{i}, i=1,2$, and
(2) there is a branch of $f=0$ splitting the plane into two connected components, each of them containing one branch of $\mathcal{H}_{i}$.
As the upper branch of $\mathcal{H}_{2}$ crosses the two branches of $\mathcal{H}_{1}$, this is impossible. This provides a contradiction to the existence of an $H$-closure for $T$, finishing the proof of Proposition 4.4.

Associated to the group $\dot{F} / T$ of the preceding proposition is the "abstract Witt ring" of $T$-forms (see [Ma]), which is actually the reduced Witt ring $W_{\text {red }}(F)$. (See also [L2, Chapter 1] for the definition of $W_{\text {red }}(F)$.) From Proposition 4.4 we can show there is no extension $F \longrightarrow K$ with $W_{\text {red }}(K) \cong W(K)$ such that the induced homomorphism $W_{\text {red }}(F) \longrightarrow W_{\text {red }}(K)$ is an isomorphism. Note that $W_{\text {red }}(F)$ might actually be isomorphic to $W(K)$ for some field $K$ not related to $F$, as shown in Example 8.14. This is why we can view this result as a weak version of the "unrealizability" of $W_{\text {red }}(F)$ as a "true" Witt ring. (See [Ma], as well as [Cr2].)
Actually T. Craven kindly called our attention to [Cr2, Theorem 5.5], which can be applied to obtain the following more general result.

Proposition 4.5 (Craven). Let $F=L(X)$ where $L$ is a formally real field, which is not a pythagorean field. Then for each pythagorean field extension $K / F$, the natural homomorphism $W_{\text {red }}(F) \longrightarrow W_{\text {red }}(K)=W(K)$ induced by the inclusion map $F \longrightarrow K$ is not an isomorphism.
Proof. Assume that $K$ is a pythagorean field extension of $F=L(X)$, where $L$ is a formally real field which is not pythagorean, and suppose that the field extension $F \longrightarrow K$ induces an isomorphism $W_{\text {red }}(F) \longrightarrow W_{\text {red }}(K)$.
Because $L$ is not a pythagorean field, there exists an element $l=l_{1}^{2}+l_{2}^{2}, l_{1}, l_{2} \in L$ such that $l \notin \dot{L}^{2}$. Because $K$ is a pythagorean field, there exists an element $k \in \dot{K}$ such that $k^{2}=l$. Hence the polynomial $f(X)=X^{2}-l$ has a root in $K$. Then from [Cr2, Theorem $5.5(\mathrm{~b})$ ], we see that $f(X)$ has exactly one root in every real closure of $L$. Of course this is not true, as each real closure of $L$ must contain both roots of $f(X)$. Hence we have arrived at a contradiction, completing the proof.
Of course we may take $L=\mathbb{R}(Y)$ and get the result for $\mathbb{R}(X, Y)$.
In the other direction we present a case below, where $(F, T)$ admits a maximal preordered $T$-extension $\left(\dot{K}, \dot{K}^{2}\right)$. We recall that a preordering $T$ in $F$ is SAP (Strong Approximation Property) if and only if for each pair of elements $a, b \in$ $\dot{F}$ there exists an element $c \in \dot{F}$ such that $D_{F}(a, b) \cap \hat{T}=D_{F}(c) \cap \hat{T}$. (Here as above, $\hat{T}$ is the set of all orderings $\alpha \in X(F)$ such that $T \subset \alpha$.) If $T$ is SAP and $R$ is a preordering of $F$ containing $T$, then $R$ is SAP as well. (See
[L2, Theorem 17.12 and Corollary 16.8].) Note that this definition implies that every finite union of basic open sets in $X(F)$ is a "principal" set $D_{F}(c)$.
Proposition 4.6. Let $F$ be a formally real field, and let $T$ be a SAP preordering in $F$. Then $(F, T)$ admits a maximal preordered $T$-extension ( $K, \dot{K}^{2}$ ), which is again SAP.

Proof. Let $F$ be a formally real field and let $T$ be a SAP preordering in $F$. Using Zorn's lemma we see that there exists a $T$-extension $(L, S)$ of $(F, T)$ which is maximal among the preordered $T$-extensions. We claim that $S$ is a SAP preordering in $L$. In order to show this, pick any elements $a, b \in \dot{L}$. Because $(L, S)$ is a $T$-extension of $(F, T)$ we see that there exist elements $a^{\prime}, b^{\prime} \in \dot{F}$ such that $a a^{\prime}, b b^{\prime} \in S$. Because $T$ is SAP there exists an element $c \in \dot{F}$ such that $D_{F}\left(a^{\prime}, b^{\prime}\right) \cap \hat{T}=D_{F}(c) \cap \hat{T}$. Let $\alpha \in D_{L}(c) \cap \hat{S}$ and $\beta=\alpha \cap F$, then $\beta \in \hat{T}$ and $c \in \beta$. Thus $a^{\prime}, b^{\prime} \in \beta \subset \alpha$ and $\alpha \in D_{L}\left(a^{\prime}, b^{\prime}\right) \cap \hat{S}$. Conversely, if $\alpha \in D_{L}\left(a^{\prime}, b^{\prime}\right) \cap \hat{S}$, then $\beta \in D_{F}\left(a^{\prime}, b^{\prime}\right) \cap \hat{T}=D_{F}(c) \cap \hat{T}$ and $\alpha \in D_{L}(c) \cap \hat{S}$. Since it is clear that $D_{L}(a, b) \cap \hat{S}=D_{L}\left(a^{\prime}, b^{\prime}\right) \cap \hat{S}$, we have shown that $D_{L}(a, b) \cap \hat{S}=$ $D_{L}(c) \cap \hat{S}$ and that $S$ is SAP.
Now, we just have to prove that $S=\dot{L}^{2}$. Suppose it is not true. Then there exists an element $s \in S \backslash \dot{L}^{2}$ and we can set $E=L(\sqrt{s})=L[Z] /\left(Z^{2}-s\right)$. Let $\alpha$ be an ordering of $L$ containing $S$. We know there are two orderings $\alpha_{1}, \alpha_{2}$ on $E$ extending $\alpha$ and giving opposite signs to $z$. Denote by $\alpha_{1}$ the ordering containing $z$.
Define $P$ as $\bigcap_{S \subseteq \alpha} \alpha_{1}$, then $P \cap L=\bigcap_{S \subseteq \alpha}\left(\alpha_{1} \cap L\right)=\bigcap_{S \subseteq \alpha}(\alpha)=S$ and we have proved that $\dot{L} / S \longrightarrow \dot{E} / P$ is one-to-one. Take $h=a+b z \in E$ with $a, b \in L$. Because $S$ is SAP we know there exists $g \in L$ such that $\left[D_{L}(N(h), a) \cup D_{L}(-N(h), b)\right] \cap \hat{S}=D_{L}(g) \cap \hat{S}$.
Let us show $g h \in P$. Suppose $S \subset \alpha$, then $g \in \alpha_{1} \Longleftrightarrow g \in \alpha \Longleftrightarrow[N(f), a \in$ $\alpha]$ or $[-N(f), b \in \alpha] \Longleftrightarrow h \in \alpha_{1}$. Thus $g h \in \bigcap_{S \subseteq \alpha} \alpha_{1}=P$ and $\dot{L} / S \longrightarrow \dot{E} / P$ is onto.
But then $(E, P)$ is a strict preordered $T$-extension of $(L, S)$, contradicting the maximality of $(L, S)$. This proves $S=\dot{L}^{2}$ and finishes the proof of the proposition.

According to [ELP], we say that a field $F$ satisfies the property $H_{4}$ if each totally indefinite quadratic form of dimension four represents zero in $F$. When a formally real field $F$ satisfies $H_{4}$, the nonzero sums of squares in $F$ form a SAP preordering. By [ELP, Theorem F], every field $F$ such that $F(\sqrt{-1})$ is $C_{1}$ (i. e. "quasi-algebraically closed") satisfies $H_{4}$.
Therefore the preceding proposition will apply in particular to any formally real field of transcendence degree 1 over a real closed field. But in this case one can even prove the following addition to Proposition 4.6.
Proposition 4.7. Let $F$ be a formally real field which satisfies $H_{4}$, and let $T$ be the set of nonzero sums of squares in $F$. Let $T=P_{H}$ for some essential subgroup $H$ of $\mathcal{G}_{F}$. Then $(F, T)$ admits an $H$-closure $\left(L, \dot{L}^{2}\right)$.

Because we shall not use this result in this paper, and because our proof is quite long, we shall omit its details.

## §5. Cyclic subgroups of $W$-groups

In this section we consider the subgroups $H$ of $\mathcal{G}_{F}$ which are the easiest to understand in terms of their associated $H$-orderings, namely the two cyclic groups $C_{2}$ and $C_{4}$. As mentioned earlier, $C_{2}$ in many ways is the motivating example for this entire theory, and we cite here the results previously given in [MiSp1] for this group, as a means of illustrating the results we are attempting to generalize in this paper. As any single element of $\mathcal{G}_{F}$ necessarily generates a cyclic subgroup of order 2 or 4 , those which generate subgroups of order 4 are precisely those not associated with usual orderings on the field $F$. These are the so-called half-orders of $F$, as investigated in [K1]; this concept was first introduced by Sperner [S] in 1949, in a geometrical context.

Definition 5.1. A nonsimple involution of $\mathcal{G}_{F}$ is an element $\sigma \in \mathcal{G}_{F}$ such that $\sigma^{2}=1$ and $\sigma \notin \Phi\left(\mathcal{G}_{F}\right)$. In other words, a nonsimple involution is an element of $\mathcal{G}_{F}$ which generates an essential subgroup of order 2.

Theorem 5.2. [MiSp1] The field $F$ is formally real if and only if $\mathcal{G}_{F}$ contains a nonsimple involution. There is a one-one correspondence between orderings on $F$ and nontrivial cosets of $\Phi\left(\mathcal{G}_{F}\right)$ which have an involution as a coset representative.

We have the well-known characterization of those subgroups of $\dot{F}$ that are orderings, which we include here for the sake of completeness.

Proposition 5.3. A subgroup $S$ of $\dot{F}$ containing $\dot{F}^{2}$ is a $C_{2}$-ordering of $F$ if and only if the following conditions hold.
(1) $|\dot{F} / S|=2$ and
(2) $1+s \in S \forall s \in S$.

We can now characterize those subgroups $S$ of $\dot{F}$ which are $C_{4}$-orderings. They are precisely those subgroups of index 2 which fail to be orderings. We also see that $C_{4}$-ordered fields always admit a closure.
Proposition 5.4. A subgroup $S$ of $\dot{F}$ containing $\dot{F}^{2}$ is a $C_{4}$-ordering of $F$ if and only if the following conditions hold.
(1) $|\dot{F} / S|=2$ and
(2) $\exists s \in S$ such that $1+s \notin S$.

Proof. We know $S$ is a $C_{4}$-ordering of $F$ if and only if there exists $\sigma \in \mathcal{G}_{F}$ such that $S=\left\{a \in \dot{F} \mid \sqrt{a}^{\sigma}=\sqrt{a}\right\}$ where $\sigma^{2} \neq 1$. Now any subgroup of index 2 in $\dot{F}$ is of the form $\left\{a \in \dot{F} \mid \sqrt{a}^{\sigma}=\sqrt{a}\right\}$ for some $\sigma \in \mathcal{G}_{F}$, so we need only guarantee that $S$ is not an ordering, which condition (2) does.

Remark 5.5.
(1) Note that it is easy to see that condition (2) above can be replaced by (2') $S+S=\dot{F}$. (Recall that here we use our definition of the sum $S+S$ as described in the beginning of $\S 3$. If instead we set the sum $S \oplus S$ as $\left\{s_{1}+s_{2} \mid s_{1}, s_{2} \in S\right\}$ then we can replace (2) by the condition $\dot{F} \subset S \oplus S$ provided that $F$ contains more than five elements. (See [K1, Remark after Def. 1.1].)
(2) There are actually two kinds of $C_{4}$-orderings, distinguished by whether or not they contain -1 . If $S$ is a $C_{4}$-ordering such that $-1 \in S$, we say that $S$ has level 1 . The prototype is given by $\dot{\mathbb{F}}_{p}^{2}$ when $p \equiv 1 \bmod 4$. If $-1 \notin S$, then necessarily $-1 \in S+S$, and we say that $S$ has level 2 . The model is $\dot{\mathbb{F}}_{p}^{2}$ when $p \equiv-1 \bmod 4$. It is clear that every $C_{4}$-extension preserves the level.

Proposition 5.6. Let $\left(K, \dot{K}^{2}\right)$ be a maximal $T$-extension of a $C_{4}$-ordered field $(F, T)$. Then
(1) $K$ is characterized by the condition of being maximal in $F(2)$ among fields $L \supseteq F$ such that $\sqrt{a} \notin L \forall a \in \dot{F} \backslash T$.
(2) $\mathcal{G}_{K} \cong C_{4}$.
(3) $\operatorname{Gal}(K(2) / K) \cong \mathbb{Z}_{2}$, the group of 2-adic integers.

In particular, every maximal $T$-extension of a $C_{4}$-ordered field $(F, T)$ is a $C_{4}$ closure, and thus $C_{4}$-closures always exist.
Proof. Let $\left(K, \dot{K}^{2}\right)$ be a maximal $T$-extension of the $C_{4}$-ordered field $(F, T)$. Since $\dot{K}^{2} \cap F=T$, we see that for any $a \in \dot{F} \backslash T$, we have $\sqrt{a} \notin K$, while for any $a \in T$, we have $\sqrt{a} \in K$. Now if $L \supsetneq K$ in $F(2)$, then $L \supseteq K(\sqrt{a})$ for some $a \in \dot{K} \backslash \dot{K}^{2}$. Since the cosets of $\dot{K}^{2}$ in $\dot{K}$ correspond naturally to the cosets of $T$ in $\dot{F}$, we see that $L$ contains $\sqrt{a^{\prime}}$ for some $a^{\prime} \in \dot{F} \backslash T$, and thus $K$ is maximal among such extensions of $F$ in $F(2)$. Conversely, suppose $K$ is maximal in $F(2)$ among fields $L \supseteq F$ such that $\sqrt{a} \notin L \forall a \in F \backslash T$. Then we see that $\dot{K}^{2} \cap F=T$. We need to see that $\left|\dot{K} / \dot{K}^{2}\right|=2$. Suppose it is not true. Fix $a \in \dot{F} \backslash T$, so that $a \notin \dot{K}^{2}$, and suppose there exists some $b \in \dot{K}$ such that $a, b$ are linearly independent in $\dot{K} / \dot{K}^{2}$. Then certainly $b \notin a T$, and setting $L=K(\sqrt{b})$ contradicts the maximality of $K$. Thus we have that $\left(K, \dot{K}^{2}\right)$ is a maximal $T$-extension for $(F, T)$, and this proves (1).
Now observe that $\mathcal{G}_{K}$ is generated by one generator, since $\left|\dot{K} / \dot{K}^{2}\right|=2$, so $\mathcal{G}_{K} \cong C_{2}$ or $C_{4}$. It cannot be $C_{2}$, or else $T$ would be an ordering on $F$. Thus $\mathcal{G}_{K} \cong C_{4}$. Finally, $\operatorname{Gal}(K(2) / K)$ is cyclic and cannot be finite, since it is not $C_{2}$ (see [Be]). Thus $\operatorname{Gal}(K(2) / K) \cong \mathbb{Z}_{2}$.

## §6. Subgroups of $W$-groups generated by two elements

As we saw in Theorem 2.5, a group generated by two elements appearing as a subgroup of $\mathcal{G}_{F}$ may only be one in the list $C_{2} * C_{4}, C_{4} * C_{4}, C_{2} * C_{2}, C_{4} \times$ $C_{4}, C_{4} \rtimes C_{4}$. The last two are particular cases of the groups studied in $\S 7$ and
§ 8, and we will focus in this section on the first three. The third one is better known as the dihedral group $D$.
We will give an algebraic characterization for the orderings associated with these groups and show that it is always possible to make closures. Portions of the proofs rely on the characterizations of $C_{4} \times C_{4}$ - and $C_{4} \rtimes C_{4}$-orderings obtained in $\S 7$; but since the results in $\S 7$ do not rely on those in $\S 6$, we freely use these results where needed.
Lemma 6.1. Let $T$ be a subgroup of $\dot{F}$ such that $\dot{F}^{2} \subseteq T$ and $|\dot{F} / T|=4$. If $-1 \notin T$, then $F$ is $(T \cup-T)$-rigid.
Proof. Let $\dot{F} / T=\{1,-1, a,-a\}$. Then $(T \cup-T)+a(T \cup-T) \subseteq(T \cup-T) \cup$ $a(T \cup-T)=\dot{F}$.
Proposition 6.2. A subgroup $T$ of $\dot{F}$ is a $C_{2} * C_{4}$-ordering if and only if $\dot{F}^{2} \subseteq T,|\dot{F} / T|=4$, and the following two conditions hold.
(1) $T+T \neq T$, and
(2) $-1 \notin \sum T$, where $\sum T$ denotes the set of all finite sums of elements of $T$.

Proof. The conditions $\dot{F}^{2} \subseteq T$ and $|\dot{F} / T|=4$ are necessary and sufficient for $T$ to be a $G$-ordering for some essential subgroup $G \subseteq \mathcal{G}_{F}$ generated by two elements $\sigma, \tau$, independent $\bmod \Phi\left(\mathcal{G}_{F}\right)$. We next show the necessity of conditions (1) and (2). Let $G \cong C_{2} * C_{4}$ be a subgroup of $\mathcal{G}_{F}$, where $T=P_{G}$. We assume $G$ is generated by two noncommuting (hence independent $\bmod \Phi\left(\mathcal{G}_{F}\right)$ ) elements $\sigma, \tau$ such that $\sigma^{2}=1, \tau^{4}=1$. If $T+T=T$, then by Proposition 6.14, $T$ would be a $D$-ordering (this is independent of previous results). Since it is not, we see that (1) holds. Also $-T \nsubseteq \sum T$, since $\sum T \subseteq P_{\sigma}$, which is an ordering because $\sigma$ is an involution. Thus $P_{\sigma}$ cannot contain $-T$ and condition (2) holds.

We now show the sufficiency of the conditions. Since $T$ is a $G$-ordering for some essential subgroup with two generators, it must be isomorphic to one of the five groups listed in Theorem 2.5. Since $-1 \notin T$ by (2), it cannot be $C_{4} \times C_{4}$ by Proposition 7.2 in the next section. Also (1) shows that $G$ cannot be isomorphic to $D \cong C_{2} * C_{2}$ by Proposition 6.14 , and (2) shows that $G$ cannot be isomorphic to $C_{4} \rtimes C_{4}$ by Proposition 7.6. Finally, from (1) and (2) we can see that $\sum T$ is an ordering on $F$, since it is clearly a proper subgroup of $\dot{F}$, which properly contains $T$, so must be of index 2 in $\dot{F}$; it does not contain -1 , and it is closed under addition. Then $\sum T=T \cup a T$ for some $a \notin T$, and $G$ is generated by elements $\sigma, \tau$ where the intersection of the fixed field of $\sigma$ with $F^{(2)}$ is $K(\sqrt{a})$, and the intersection of the fixed field of $\tau$ with $F^{(2)}$ is $K(\sqrt{-1})$. Then $P_{\sigma}=\sum T$ is an ordering, so $\sigma$ is an involution. This shows $G$ cannot be isomorphic to $C_{4} * C_{4}$. Thus the only remaining possibility is $G \cong C_{2} * C_{4}$.
Proposition 6.3. A subgroup $T$ of $\dot{F}$ is a $C_{4} * C_{4}$-ordering if and only if $\dot{F}^{2} \subseteq T,|\dot{F} / T|=4$, and one of the following two conditions hold.
(1) $-1 \in T$ and $F$ is not $T$-rigid, or
(2) $-1 \notin T,-1 \in \sum T$, but $T+T \neq T \cup-T$.

Proof. If $-1 \in T$, the only possible subgroups $H$ of $\mathcal{G}_{F}$ with two generators for which $T$ can be an $H$-ordering are $C_{4} \times C_{4}$ and $C_{4} * C_{4}$. The other three are eliminated by Propositions $6.14,6.2$, and 7.6 . Also, if $-1 \in T$, then $F$ is $T$-rigid if and only if $T$ is a $C_{4} \times C_{4}$-ordering by Proposition 7.2. This leaves $C_{4} * C_{4}$ as the only possibility.
If $-1 \notin T$, there are three possibilities to consider: $-1 \notin \sum T, T+T=T \cup-T$, or $-1 \in \sum T$ but $T+T \neq T \cup-T$. The first case occurs if and only if $T$ is either a $D$-ordering (by Proposition 6.14) or a $C_{2} * C_{4}$-ordering (by Proposition 6.2). The second case occurs if and only if $T$ is a $C_{4} \rtimes C_{4}$-ordering by Proposition 7.6 and Lemma 6.1. Thus, the third case must occur if and only if $T$ is a $C_{4} * C_{4}$-ordering as claimed.
The following example constructs a $C_{4} * C_{4}$-ordering of $\mathbb{Q}_{2}$. It is illustrative, in that it shows how even in a relatively "small" setting, the additive structure of $T$ can behave quite differently from the additive structure of $\dot{F}(\sqrt{T})^{2}$. In particular, it shows that $\langle 1,1\rangle$ may represent elements in $F(\sqrt{T})$ which are not in $T+T$. In this example, $T+T$ is not multiplicatively closed, but of course the form $\langle 1,1\rangle$, being a Pfister form, is multiplicative in $F(\sqrt{T})$.
Example 6.4. In $F=\mathbb{Q}_{2}$ consider the subgroup $T=\dot{F}^{2} \cup 5 \dot{F}^{2}$ of $\dot{F}$. Using the notation for $\mathcal{G}_{2}$ as in Example 2.9, we see that the corresponding subgroup of $\mathcal{G}_{2}$ is $H=\langle\sigma, \tau\rangle \cong C_{4} * C_{4}$. This is a W-group associated with the Witt ring $\mathbb{Z} / 4 \mathbb{Z} \times{ }_{M} \mathbb{Z} / 4 \mathbb{Z}$, where the product " $\times_{M}$ " is taken in the category of Witt rings (see [Ma] and [MiSm2]). The fixed field of $H$ is $K=\mathbb{Q}_{2}(\sqrt{5})$. The form $\langle 1,1\rangle$ represents -1 over $K$, and this can be shown as follows. It is well known and easy to show that for any quadratic field extension $F \longrightarrow K=F(\sqrt{a})$, one has $\left(K^{2}+K^{2}\right) \cap \dot{F}=\left(F^{2}+F^{2}\right)\left(F^{2}+a F^{2}\right)$. If $F=\mathbb{Q}_{2}$ and $a=5$, we have $30=5 \times 6 \in\left(K^{2}+a K^{2}\right)$ and $2 \in\left(K^{2}+K^{2}\right)$. Then $15 \in K^{2}+K^{2}$, and since 15 is congruent to $-1 \bmod 16$ : it is a negative square in $\mathbb{Q}_{2}$. This shows that $-1 \in K^{2}+K^{2}$.
However, when one considers which elements of $\dot{F} / \dot{F}^{2}$ are in $T+T$, one finds only the six classes represented by $1,2,5,10,-2,-10$. In particular, $-1 \notin T+T$, and $T+T$ is not multiplicatively closed (so forms mod $T$-equivalence do not behave as quadratic forms over a field behave). Nonetheless, it is easy to see that $-1 \in T+T+T$, so that $T+T \neq T \cup-T$, but $-1 \in \sum T$, consistent with the proposition above.
In $\S 9$ we introduce natural conditions for a subgroup $H$ of $\mathcal{G}_{F}$ in order to keep track of the additive properties of $\dot{F} / T$ under 2-extensions. We shall see in $\S 9$ that the group $H \subset \mathcal{G}_{F}$ above does not possess one of the key properties we require.
Theorem 6.5. $A\left(C_{2} * C_{4}\right)$-ordered field $(F, T)$ admits a closure.
Proof. Let $\mathcal{S}$ be the set of extensions $(L, S)$ of $(F, T)$ inside $F(2)$ satisfying the additional condition that $-1 \notin \sum S$. As in the proof of Proposition 4.1, we
see that $\mathcal{S}$ has a maximal element $\left(K, T_{0}\right)$ with $\dot{K} / T_{0} \cong \dot{F} / T, T=T_{0} \cap F$, and $-1 \notin \sum T_{0}$. Then $\left(K, T_{0}\right)$ is a $\left(C_{2} * C_{4}\right)$-ordered field. To see this we need only show that conditions (1) and (2) of Proposition 6.2 hold, and condition (2) is given by construction of $\left(K, T_{0}\right)$. Condition (1) holds since if $T_{0}+T_{0}=T_{0}$, then $T+T \subseteq\left(T_{0}+T_{0}\right) \cap F=T_{0} \cap F=T$, contradicting the fact that $T$ is a $C_{2} * C_{4}$-ordering on $F$.
To conclude, we must show $T_{0}=\dot{K}^{2}$. Notice $\sum T_{0}$ is an ordering on $K$, so $K$ is formally real. We may write $\dot{K} / T_{0}=\left\{ \pm T_{0}, \pm a T_{0}\right\}$, where $a \in T+T$. If $T_{0} \neq \dot{K}^{2}$, we can choose $c \in T-\dot{K}^{2}$, and consider $L=K(\sqrt{c})$. Since $-c \notin \sum T_{0}, \sum T_{0}$ extends to an ordering $S_{0}$ on $L$. Then $S_{0} \cup-S_{0}=\dot{L}$ and $a \in S_{0}$. Let $S$ be a subgroup of $S_{0}$ containing $T_{0}$ and maximal with respect to excluding $a$. Then $\dot{L} / S=\{ \pm S, \pm a S\} \cong \dot{K} / T_{0} \cong \dot{F} / T$. Also $S \cap K \supseteq T_{0}$ by construction, and if there exists $b \in S \cap K, b \notin T_{0}$, then $b \in a T_{0} \cup-T_{0} \cup-a T_{0}$, which implies either $a \in S$ or $-1 \in S$, which leads to a contradiction in either case. Thus $S \cap K=T_{0}$, and $(L, S)$ is an extension contradicting the maximality of $\left(K, T_{0}\right)$. We conclude $T_{0}=\dot{K}^{2}$.

Theorem 6.6. $A\left(C_{4} * C_{4}\right)$-ordered field $(F, T)$ admits a $\left(C_{4} * C_{4}\right)$-closure $\left(K, \dot{K}^{2}\right)$.

Proof. Let $\left(K, \dot{K}^{2}\right)$ be a maximal $T$-extension for $(F, T)$. First assume $-1 \in T$. We must show $K$ is not a rigid field. Let $\{1, a, b, a b\}$ be a set of representatives for $\dot{F} / T$ that lifts to a set of representatives for $\dot{K} / \dot{K}^{2}$. Since $F$ is not $T$-rigid, we may, without loss of generality, assume $b \in T+a T$. Then $T+a T \subseteq \dot{K}^{2}+a \dot{K}^{2}$, but $b \notin \dot{K}^{2} \cup a \dot{K}^{2}$, so $K$ is not rigid, and $\dot{K}^{2}$ is a $\left(C_{4} * C_{4}\right)$-ordering on $K$.
Now assume $-1 \notin T=F \cap \dot{K}^{2}$. Then $-1 \notin \dot{K}^{2}$, and $-1 \in \sum T \subseteq \sum \dot{K}^{2}$. Letting $\{1,-1, a,-a\}$ be a set of representatives for $\dot{F} / T$, this again lifts to a set of representatives for $\dot{K} / \dot{K}^{2}$. Since $T+T \neq T \cup-T$, but clearly also $T+T \neq T$, we may assume $a \in T+T$, so $a \in \dot{K}^{2}+\dot{K}^{2}$ as well. This shows $\dot{K}^{2}$ is a $\left(C_{4} * C_{4}\right)$-ordering on $K$.

Remark 6.7. We have defined in Definition 3.2 the level of an $H$-ordering. It is then easy to see that the level of a $\left(C_{4} * C_{4}\right)$-ordering $T$ is at most 4. The level of the closure $K$ (which is the "usual" level) is less than or equal to the level of $T$. The level of a ( $C_{4} * C_{4}$ )-closure is either 1 or 2 , as any field of finite level with at most four square classes has level at most 2 . The level of $T$ is 1 if and only if the level of $K$ is 1 , but in the other cases the level may actually decrease: Example 6.4 shows that $T$ has level 3 and that its closure has level 2.

Now we turn our attention to $D$-orderings. We showed in § 2 that $C_{2} \times C_{2}$ cannot be an essential subgroup of $\mathcal{G}_{F}$, so if $H$ is an essential subgroup of $\mathcal{G}_{F}$ generated by two elements of order 2 , necessarily $H \cong D$. Recall that according to [ Br ], a 2-element fan in $F$ is a set of two distinct orderings $P_{1}, P_{2}$ on $F$, and it can be identified with the preordering $T=P_{1} \cap P_{2}$.

Lemma 6.8. The dihedral group $D$ is a subgroup of $\mathcal{G}_{F}$ if and only if there is a 2-element fan in $F$. In this case, $T \subseteq \dot{F}$ is a $D$-ordering if and only if $T$ is a 2-element fan in $F$.

Proof. Let $H=\left\langle\sigma, \tau \mid \sigma^{2}=\tau^{2}=[\sigma, \tau]^{2}=1\right\rangle \cong D$ be a subgroup of $\mathcal{G}_{F}$. Then $P_{\sigma}$ and $P_{\tau}$ are positive cones of two distinct orderings on $F$, and $P_{H}=P_{\sigma} \cap P_{\tau}$. Conversely, if $P_{1}, P_{2}$ are positive cones corresponding to distinct orderings on $F$, then there exist nontrivial involutions $\sigma, \tau \in \mathcal{G}_{F}$, in distinct cosets of $\Phi\left(\mathcal{G}_{F}\right)$, such that $P_{1}=P_{\sigma}$ and $P_{2}=P_{\tau}$. Then $H=\langle\sigma, \tau\rangle$ is an essential subgroup of $\mathcal{G}_{F}$, and $H \cong D$.

In [BEK], a field $F$ with two orderings $P_{1}, P_{2}$ is defined to be maximal with respect to $P_{1}, P_{2}$ if for any algebraic extension $K$ of $F$, at least one of the two orderings cannot be extended to $K$. Since we prefer to work inside $F(2)$, we modify this as follows.

Definition 6.9. A field $F$ with two orderings $P_{1}, P_{2}$ is maximal with respect to $P_{1}, P_{2}$ if for any 2-extension $K$ of $F$, at least one of the orderings does not extend to $K$.

Proposition 6.10. ( $F, P_{1}, P_{2}$ ) is maximal if and only if $\left(F, T_{F}\right)$ is a $D$-ordered field, where $T_{F}=P_{1} \cap P_{2}$, and there exists no proper $D$-ordered extension field $\left(L, T_{L}\right) \subseteq F(2)$ with $T_{L} \cap F=T_{F}$.

Proof. Suppose that the field ( $F, P_{1}, P_{2}$ ) is maximal. Let $\sigma_{1}, \sigma_{2}$ be involutions in $\mathcal{G}_{F}$ such that $P_{i}=\left\{a \in \dot{F} \mid \sqrt{a}^{\sigma_{i}}=\sqrt{a}\right\}, i=1,2$. Then the subgroup $\left\langle\sigma_{1}, \sigma_{2}\right\rangle \subseteq \mathcal{G}_{F}$ is isomorphic to $D$, as we have seen, and $\left(F, T_{F}\right)$ is a $D$-ordered field as claimed.
Now suppose that $L$ is a $D$-ordered field containing $F$ inside $F(2)$, such that $T_{L} \cap F=T_{F}$. Then $\mathcal{G}_{L}$ contains a subgroup isomorphic to $D$, which we can take to be generated by two involutions $\tau_{1}, \tau_{2}$ such that $T_{L}=Q_{1} \cap Q_{2}$, where $Q_{i}=\left\{a \in \dot{L} \mid \sqrt{a}^{\tau_{i}}=\sqrt{a}\right\}, i=1,2$ are distinct orderings of $L$. Now $Q_{i} \cap F \supseteq T_{L} \cap F=T_{F}$, so $Q_{i} \cap F$ is an ordering of $F$ which contains $T_{F}, i=1,2$. Thus $\left\{Q_{1} \cap F, Q_{2} \cap F\right\}=\left\{P_{1}, P_{2}\right\}$. Then by maximality of ( $F, P_{1}, P_{2}$ ), we see $L=F$.
Conversely, suppose that $F$ is a $D$-ordered field contained in no proper $D$ ordered extension field as described. Then $F$ has at least two distinct orderings $P_{1}$ and $P_{2}$ corresponding to the two involutions generating the subgroup $D$ of $\mathcal{G}_{F}$, and since there is no proper $D$-ordered extension field, we see that it is not possible for both orderings to extend to any extension of $F$. Thus ( $F, P_{1}, P_{2}$ ) is maximal, as claimed.

By Zorn's Lemma we immediately see the following.
Proposition 6.11. [BEK, Prop.3] Given a field $F$ with two orderings $P_{1}, P_{2}$, there always exists an algebraic extension $\tilde{F}$ of $F$ which is maximal with respect to $\tilde{P}_{1}, \tilde{P}_{2}$, where $\tilde{P}_{1}, \tilde{P}_{2}$ are extensions of $P_{1}, P_{2}$ to $\tilde{F}$.

Theorem 6.12. A field $\left(F, P_{1}, P_{2}\right)$ is maximal if and only if
(1) there exist exactly two orderings on $F$ and
(2) $F$ is pythagorean, i.e. any sum of squares is a square in $F$.

Proof. [BEK] Suppose three different orderings $P_{1}, P_{2}, P_{3}$ are possible in $F$. Let $x \in \dot{F}$ be such that $x$ is positive with respect to the first two orderings, and negative with respect to $P_{3}$. Then $\sqrt{x} \notin F$, so $F(\sqrt{x})$ is a proper algebraic extension of $F$, and since $x$ is positive with respect to $P_{1}$ and $P_{2}$, they extend to $F(\sqrt{x})$, and $\left(F, P_{1}, P_{2}\right)$ cannot be maximal. Similarly, if $\alpha, \beta$ are elements of $F$ such that $\sqrt{\alpha^{2}+\beta^{2}} \notin F$, then $P_{1}, P_{2}$ can be extended to the proper extension $F\left(\sqrt{\alpha^{2}+\beta^{2}}\right)$ of $F$, again contradicting maximality. Thus conditions (1) and (2) are necessary.

Conversely, one can show that any field $F$ satisfying conditions (1) and (2) has $\dot{F} / \dot{F}^{2}=\{1,-1, a,-a\}$ for some $a \in \dot{F}$. Now let $F$ be such a field and let $P_{1}, P_{2}$ be the two unique orderings in $F$, so that $a$ is positive with respect to $P_{1}$ and negative with respect to $P_{2}$. Suppose $\left(F, P_{1}, P_{2}\right)$ were not maximal, and let $K=F(\sqrt{b})$ be a proper quadratic extension of $F$ such that both $P_{1}$ and $P_{2}$ extend to $K$. Since $K$ is an ordered proper extension of $F, b \neq 1,-1 \in \dot{F} / \dot{F}^{2}$, so $b=a$ or $-a$. Then either $\sqrt{a} \in K$ or $\sqrt{-a} \in K$, so that not both $P_{1}$ and $P_{2}$ extend to $K$. This is a contradiction.

Corollary 6.13. The $D$-ordered field $(F, T)$ is a maximal $D$-ordered field if and only if $\mathcal{G}_{F} \cong D$. Thus any $D$-ordered field admits a $D$-closure.
Proof. By the preceding theorem, if $F$ is maximal, it has exactly two orderings, so $\mathcal{G}_{F}$ has exactly two involutions which are independent $\bmod \Phi\left(\mathcal{G}_{F}\right)$. Also $F$ is pythagorean, so by $[\mathrm{MiSp} 1] \mathcal{G}_{F}$ is generated by involutions. Thus $\mathcal{G}_{F}$ is generated by two elements of order 2 , and since $\mathcal{G}_{F}$ is necessarily an essential subgroup of itself, we see that $\mathcal{G}_{F} \cong D$.
Conversely, if $\mathcal{G}_{F} \cong D$, then $F$ is a $D$-ordered field, and since orderings on $F$ correspond to independent involutions in $\mathcal{G}_{F}$, we see that $F$ has precisely two distinct orderings. Also, since $\mathcal{G}_{F}$ is generated by these involutions, we see that $F$ is pythagorean. Thus, by the preceding theorem, $F$ is a maximal $D$-ordered field. Then we see that for any $D$-ordered field $\left(L, P_{H}\right)$, a maximal $D$-ordered extension $\left(F, \dot{F}^{2}\right)$ containing $\left(L, P_{H}\right)$ will be a closure for $\left(L, P_{H}\right)$.
Proposition 6.14. A subgroup $S$ of $\dot{F}$ containing $\dot{F}^{2}$ is a $D$-ordering of $F$ if and only if $|\dot{F} / S|=4$ and $1+s \in S$ whenever $s \in S$.

Proof. All that is necessary for $S$ to be a $D$-ordering of $F$ is that it be a 2 element fan in $F$. In other words, $S$ must be a preordering of index 4 in $F$. A subgroup $S$ of $\dot{F}$ is such a preordering if and only if the conditions in the statement of the proposition are met.

## §7. Classification of Rigid orderings

This section will provide a full Galois-theoretic and algebraic characterization of all possible rigid orderings. We start with the following definition.

Definition 7.1. Let $I$ be a possibly empty index set. We call $G$ a $C(I)$ group if $G$ is isomorphic to $\left(C_{4}\right)^{I} \times C_{4}$, an $S(I)$-group if $G$ is isomorphic to $\left(C_{4}\right)^{I} \rtimes C_{4}$, and a $D(I)$-group if $G$ is isomorphic to $\left(C_{4}\right)^{I} \rtimes C_{2}$, the semidirect product being defined with the nontrivial action of $C_{4}$ or $C_{2}$ on each inner factor in the last two cases, when $I$ is nonempty. A $G$-ordering on $F$ is called a $C(I)$ (respectively $S(I)$-, $D(I)$-) ordering if $G$ is a $C(I)$ - (respectively $S(I)$-, $D(I)$-) group. When $I=\emptyset$ the $C(I)$ - and $S(I)$-orderings are the $C_{4}$-orderings, and the $D(I)$-orderings are the $C_{2}$-orderings, that is the usual orderings. Observe that $C(\emptyset)$ - and $S(\emptyset)$-orderings both correspond to the same group $C_{4}$. The difference between them is that a $C(\emptyset)$-ordering has level 1, while an $S(\emptyset)$-ordering has level 2. (See Remark 5.5 for comparison.) When $|I|=1$, we obtain the groups generated by two elements which are respectively $\left(C_{4}\right) \times C_{4},\left(C_{4}\right) \rtimes C_{4}$ and $D$.
In this section we will characterize $C(I)$-orderings, $S(I)$-orderings and $D(I)$ orderings in terms of their algebraic properties as subgroups of $\dot{F}$. We will see in particular that they are all rigid, and that they constitute the whole class of rigid orderings. The group $\coprod_{i \in I} G_{i}$ will denote the direct sum of the groups $G_{i}, i \in I$ and in $I \cup\{x\}$ the letter $x$ is added to denote the new index.
Proposition 7.2. A subgroup $T$ of $\dot{F}$ containing $\dot{F}^{2}$ is a $C(I)$-ordering if and only if the following three conditions hold.
(1) $-1 \in T$,
(2) $F$ is $T$-rigid, and
(3) $\dot{F} / T \cong \coprod_{i \in I \cup\{x\}}\left(C_{2}\right)_{i}$.

In other words, the $C(I)$-orderings are exactly the rigid orderings of level 1.
Proof. If $I=\emptyset$, the result follows from Proposition 5.4 and Remark 5.5, so we shall assume $I \neq \emptyset$. We begin by showing that the three conditions above are necessary. Let $G \cong C(I)$ and let $T$ be a $G$-ordering. Suppose $-1 \notin T$. Let $\left\{\sigma_{i}, i \in I ; \sigma_{x}\right\}$ generate $G$. Then $T=\cap_{i \in I \cup\{x\}} P_{\sigma_{i}}$ and $|\dot{F} / T| \geq 4$. Thus there are at least four classes $\bmod T$, which we can represent as $1,-1, a,-a$ for some $a \in \dot{F}$, and there exists a $D^{a,-a}$-extension $L$ of $F$. Hence there exist elements $\sigma, \tau \in G$ such that $a \in P_{\sigma} \backslash P_{\tau}$ and $-a \in P_{\tau} \backslash P_{\sigma}$. It then follows that the restriction of $\sigma \tau$ to $L$ has order 4 , so that $\left.\sigma\right|_{L},\left.\tau\right|_{L}$ generate $\operatorname{Gal}(L / F) \cong D$, and hence cannot commute. Yet $\sigma, \tau \in G$, which is an abelian group. This is a contradiction, so $-1 \in T$, and (1) holds.
Since $-1 \in T$, we have $T \cup-T=T$. Suppose we have a nonrigid element $c \in \dot{F} \backslash T$, so that we have $t_{1}, t_{2} \in T$ with $t_{1}+c t_{2} \notin T \cup c T$. Then $b=$ $1+c t_{2} / t_{1} \notin T \cup c T$. Let $a=-c t_{2} / t_{1} \notin T$. Then $a+b=1$, so $\left(\frac{a, b}{F}\right)$ splits. Since $b \notin T \cup c T=T \cup a T, a$ and $b$ are independent $\bmod T$ and thus $\bmod \dot{F}^{2}$. Hence we have a $D^{a, b}$-extension $L$ of $F$, and by the same argument as above, we find $\sigma, \tau \in G$ which do not commute, leading to a contradiction. Thus $F$ is $T$-rigid and (2) holds. Finally, by Kummer theory we know that $\dot{F} / T$ is isomorphic to the dual $(G / \Phi(G))^{*} \cong \coprod_{i \in I \cup\{x\}}\left(C_{2}\right)_{i}$, giving (3).
We now show that the three conditions are sufficient for $T$ to be a $C(I)$ ordering. By (3) we see that $T=\cap_{i \in I \cup\{x\}} P_{i}$ where $P_{i}$ is the kernel of the
projection $\dot{F} \rightarrow \dot{F} / T \cong \coprod_{i \in I \cup\{x\}}\left(C_{2}\right)_{i} \rightarrow\left(C_{2}\right)_{i}$. Further, for each $P_{i}$ we have a $\sigma_{i} \in \mathcal{G}_{F}$ such that $P_{i}=P_{\sigma_{i}}$. Let $G$ be the closed subgroup of $\mathcal{G}_{F}$ generated by $\left\{\sigma_{i} \mid i \in I \cup\{x\}\right\}$. Then $G \subseteq\left\{\sigma \mid P_{\sigma} \supseteq T\right\}$ because every element of $G$ must fix every $\sqrt{a}$ left fixed by the $\sigma_{i}$. So we also have $T=\cap_{\sigma \in G} P_{\sigma}$, and $T$ is a $G$-ordering. It remains to show that $G$ is a $C(I)$-group.
Since $-1 \in T \subseteq P_{\sigma_{i}}$, none of the $P_{\sigma_{i}}$ can be usual orderings on $F$, so each $\sigma_{i}$ must have exponent 4 in $G$. Since $-1 \in T$ and $F$ is $T$-rigid, we see by Proposition 3.4 that $G$ is abelian. Then $G$ is a compact abelian group of exponent 4, and $(G / \Phi(G))^{*} \cong \coprod_{i \in I \cup\{x\}}\left(C_{2}\right)_{i}$ is a discrete group of exponent 2. Then $\left((G / \Phi(G))^{*}\right)^{*} \cong G / \Phi(G) \cong \prod_{i \in I \cup\{x\}}\left(C_{2}\right)_{i}$, and $G \cong \prod_{i \in I \cup\{x\}}\left(C_{4}\right)_{i}$, so $G$ is a $C(I)$-group as claimed.
In order to characterize the subgroups of $\dot{F}$ which are $S(I)$-orderings, we will first prove three lemmas. Let $G$ be an $S(I)$-group. It will be helpful to fix the following notation: write $G=G_{1} \rtimes G_{2}$ where $G_{1} \cong \prod_{i \in I}\left(C_{4}\right)_{i}$ and $G_{2} \cong C_{4}$. Let $\tau$ be a generator of $G_{2}$ and $P_{\tau}=\left\{a \in \dot{F} \mid \sqrt{a}^{\tau}=\sqrt{a}\right\}$.
Lemma 7.3. Let $T$ be a $G$-ordering. Then $T$ has index 2 in $P_{G_{1}}$.
Proof. If $P_{G_{1}} \subseteq P_{\tau}$, we would have $T=P_{G_{1}} \cap P_{\tau}=P_{G_{1}}=P_{G}$. But by Kummer theory and the Burnside Basis Theorem, that would imply $G=G_{1}$. Thus $P_{G_{1}} \nsubseteq P_{T}, T \subsetneq P_{G_{1}}$, and $\left|P_{G_{1}} / T\right| \geq 2$. On the other hand, since $T=P_{G_{1}} \cap P_{\tau}$, we have $\left|P_{G_{1}} / T\right| \leq 2$, and so $\left|P_{G_{1}} / T\right|=2$.
Lemma 7.4. For any group homomorphism $\theta: G \rightarrow C_{4}=\langle\sigma\rangle$, we have $\theta\left(G_{1}\right) \subseteq\left\langle\sigma^{2}\right\rangle$.
Proof. If $a \in G_{1}$, writing multiplicatively, we have

$$
\theta\left(a^{-1}\right)=\theta\left(\tau a \tau^{-1}\right)=\theta(\tau) \theta(a) \theta(\tau)^{-1}=\theta(a),
$$

so $\theta(a)^{2}=1$.
Lemma 7.5. We have $T+T \subseteq P_{G_{1}}$.
Proof. Let $a \in T+T, a \notin T$, and consider the following three cases.
Case 1: $a=x^{2}+y^{2}$. Then there exists a $C_{4}^{a}$-extension $L$ of $F$, and we have a map $\theta: G \rightarrow \operatorname{Gal}(L / F) \cong C_{4}$, and by Lemma $7.4 \theta\left(G_{1}\right)$ has order at most 2 . Thus $\theta\left(G_{1}\right)$ fixes $\sqrt{a}$ and $a \in P_{G_{1}}$.
Case 2: $a=x^{2}+t, t \in T \backslash \dot{F}^{2}$. We have $a^{2}=a x^{2}+a t$, and $a$, at are independent modulo $\dot{F}^{2}$. Thus there exists a $D^{a, a t}$-extension $L$ of $F$, and $\operatorname{Gal}(L / F(\sqrt{t})) \cong$ $C_{4}$. Since $t \in T$, we have $\sqrt{t}{ }^{\sigma}=\sqrt{t}$ for $\sigma \in G$, which means we have a homomorphism $\theta: G \rightarrow \operatorname{Gal}(L / F(\sqrt{t})) \cong C_{4}$. Again applying Lemma 7.4, $\theta\left(G_{1}\right)$ has order at most 2 , so $G_{1}$ must fix $\sqrt{a}$ and $a \in P_{G_{1}}$.
Case 3: $a=s+t, s, t \in T \backslash \dot{F}^{2}$. We can write $a s^{-1}=1+t s^{-1}$, and then we are in one of the previous two cases. Hence $a s^{-1} \in P_{G_{1}}$, and it follows that $a \in P_{G_{1}}$.

Proposition 7.6. A subgroup $T$ of $\dot{F}$ containing $\dot{F}^{2}$ is an $S(I)$-ordering if and only if the following four conditions hold.
(1) $-1 \notin T$,
(2) $F$ is $(T \cup-T)$-rigid,
(3) $T+T=T \cup-T$, and
(4) $\dot{F} / T \cong \coprod_{i \in I \cup\{x\}}\left(C_{2}\right)_{i}$.

Proof. When $I=\emptyset$ the result follows from Proposition 5.4 and Remark 5.5. Thus we may assume that $I \neq \emptyset$. We begin by showing the conditions above are necessary. Condition (4) follows from Kummer theory. Condition (1) follows from Lemma 7.5 above, for if $-1 \in T$, we would have $\dot{F} \subseteq \dot{F}^{2}-\dot{F}^{2} \subseteq T-T=$ $T+T \subseteq P_{G_{1}}$, but as $|I| \geq 1$, we cannot have $P_{G_{1}}$ being all of $\dot{F}$.
To show the necessity of condition (3), first observe that $-1 \in P_{G_{1}},-1 \notin T$, and $\left|P_{G_{1}} / T\right|=2$, so $P_{G_{1}}=T \cup-T$, and thus $T+T \subseteq T \cup-T$. To show equality, we need to show that some element of $-T$ is in $T+T$. In this case, that amounts to showing that $T$ is not additively closed. Suppose that $T$ were additively closed. Then $T$ would be a preordering, so contained in some ordering $P_{\sigma}$ for some $\sigma \in \mathcal{G}_{F}$. Further, $\sigma$ is an involution not contained in $\Phi\left(\mathcal{G}_{F}\right)$, and $\sigma \in G=G_{1} \rtimes G_{2}$. In particular, $\sigma$ is not a square in $G$, and $\sigma \neq \tau$. Thus $\sigma=\sigma_{1} \tau$ for some $\sigma_{1} \in G_{1}$ and

$$
\sigma^{2}=\sigma_{1} \tau \sigma_{1} \tau=\sigma_{1} \tau \sigma_{1} \tau^{-1} \tau^{2}=\sigma_{1} \sigma_{1}^{-1} \tau^{2}=\tau^{2} \neq 1
$$

Thus $\sigma$ is not an involution, which is a contradiction, and so $-1 \in T+T$. Finally, since $F$ is $P_{G_{1}}$-rigid and $T \cup-T=P_{G_{1}}$, we see that (2) holds.
Now we must show that conditions (1) - (4) are sufficient for $T$ to be an $S(I)$ ordering. Letting $S=T \cup-T$, we see that $S$ satisfies the condition for being a $G_{1}$-ordering, with $G_{1} \cong \prod_{i \in I}\left(C_{4}\right)_{i}$, as given in Proposition 7.2. Let $Q$ be a subgroup of index 2 in $\dot{F}$ such that $T=S \cap Q$, and let $\tau \in \mathcal{G}_{F}$ such that $Q=P_{\tau}$. Let $G$ be the subgroup of $\mathcal{G}_{F}$ generated by $G_{1}$ and $\tau$. We need to see that $G=G_{1} \rtimes G_{2}$ where $G_{2}$ is the subgroup of $\mathcal{G}_{F}$ generated by $\tau$. Specifically, we need to show that $G_{1} \cap G_{2}=\{1\}$ and that $[\sigma, \tau] \sigma^{2}=1 \forall \sigma \in G_{1}$.
Since $G_{1}$ fixes $\sqrt{-1}$ and $\tau$ does not, we cannot have $\tau$ or $\tau^{-1}$ in $G_{1}$. Suppose $\tau^{2} \in G_{1}$. Then it has order 2 in $G_{1}$ and hence must be a square. Let $\sigma \in G_{1}$ such that $\sigma^{2}=\tau^{2}$. Since $P_{\sigma} \neq P_{\tau}$, there exists $a \in P_{\tau} \backslash P_{\sigma}$, and neither $a$ nor $-a$ can be a square, since neither is in $P_{\sigma}$. Since also $-1 \notin \dot{F}^{2}$, we have a $D^{a,-a}$-extension $L$ of $F$, and $\left.\sigma\right|_{L}$ has order 4 in $\operatorname{Gal}(L / F)$. However, since $\tau$ fixes $\sqrt{a},\left.\tau\right|_{L} \in \operatorname{Gal}(L / F(\sqrt{a})) \cong C_{2} \times C_{2}$, and so $\sigma^{2} \neq \tau^{2}$, contradicting the assumption. Thus $G_{1} \cap G_{2}=\{1\}$.
To prove $[\sigma, \tau] \sigma^{2}=1 \forall \sigma \in G_{1}$, it is sufficient to show that this condition holds for the restriction of $\sigma, \tau$ to each $C_{4^{-}}$and $D$-extension of $F$. Suppose $L$ is a $C_{4}^{a}{ }^{-}$ extension of $F$. Then $a$ is a sum of two squares, so $a \in T+T=T \cup-T=P_{G_{1}}$ and $\left.[\sigma, \tau] \sigma^{2}\right|_{L}=\left.\sigma^{2}\right|_{L}$. Since $\sigma \in G_{1}, \sigma \in \operatorname{Gal}(L / F(\sqrt{a}))$ and $\left.\sigma^{2}\right|_{L}=1$.
Now suppose $L$ is a $D^{a, b}$-extension of $F$. We may assume $\sigma \notin Z(\operatorname{Gal}(L / F))$ (the centralizer), since otherwise clearly $\left.[\sigma, \tau] \sigma^{2}\right|_{L}=1$. Without loss of generality,
we may assume $\sqrt{a}^{\sigma}=-\sqrt{a}$. Then $a \notin T \cup-T$, and since $1=a x^{2}+b y^{2}$, we have $b \in T-a T$, and by rigidity, $b \in T \cup-a T \cup-T \cup a T$. However, if $b$ were in $-T$ or $a T$, then we would obtain $a \in T+T=T \cup-T$, a contradiction. Thus $b \in T \cup-a T$.
If $b \in T$, then $\sigma$ and $\tau$ both fix $\sqrt{b}$ and both have order 2. If $\tau$ does not fix $\sqrt{a}$, then $\sigma, \tau$ act the same on $\sqrt{a}$ and $\sqrt{b}$ and hence commute. If $\tau$ fixes $\sqrt{a}$ then $\tau \in Z(\operatorname{Gal}(L / F))$ so in either case $[\sigma, \tau] \sigma^{2}=\sigma^{2}=1$.
If $b \in-a T$, then $\sigma$ fixes neither $\sqrt{a}$ nor $\sqrt{-a}$, so has order 4. Since $\tau$ acts differently on $\sqrt{a}$ and $\sqrt{b}$, it must fix one of them and be of order 2 , and the same holds for $\sigma \tau$. Then $[\sigma, \tau] \sigma^{2}=\sigma \tau \sigma^{-1} \tau^{-1} \sigma^{2}=\tau^{-1} \sigma^{-2} \tau^{-1} \sigma^{2}=1$ since $\sigma^{2} \in Z(\operatorname{Gal}(L / F))$.

We have another convenient formulation of Proposition 7.6 as follows:
Corollary 7.7. A subgroup $T$ of $\dot{F}$ containing $\dot{F}^{2}$ is an $S(I)$-ordering if and only if the following three conditions hold.
(a) $T$ has level 2,
(b) $F$ is $T$-rigid, and
(c) $\dot{F} / T \cong \coprod_{i \in I \cup\{x\}}\left(C_{2}\right)_{i}$.

In other words the $S(I)$-orderings are exactly the rigid orderings of level 2.
Proof. If $I=\emptyset$, the result follows from Definition 7.1, so we shall assume that $I \neq \emptyset$. Assume that $T$ satisfies (1), (2) and (3) of Proposition 7.6. We show it is rigid. Let $a \in \dot{F} \backslash(T \cup-T)$. Then $T+a T \subset(T \cup-T)+a(T \cup-T)=$ $T \cup-T \cup a T \cup-a T$. Take $s+a t \in T+a T$ and suppose it is not in $T \cup a T$. Then it is in $-T \cup-a T$. If $s+a t=-u \in-T$ then $-a=t(u+s) \in T+T=T \cup-T$, a contradiction. If $s+a t=-a u \in-a T$ then $-a=s /(u+t) \in T+T=T \cup-T$, a contradiction. Thus $T$ is rigid.
By Proposition 3.3, a rigid ordering of finite level greater than 1 is exactly a rigid ordering of level 2. This proves (a) and (b).
Conversely, if $T$ satisfies (a) and (b), then it satisfies (1) and (3) by Proposition 3.3. Let us show we also have (2). Let $a \in \dot{F} \backslash \pm(T \cup-T)=T \cup-T$. Then $(T \cup-T)+a(T \cup-T)= \pm(T+a T) \cup \pm(T-a T) \subseteq \pm(T \cup a T) \cup \pm(T \cup-a T)=$ $(T \cup-T) \cup a(T \cup-T)$. Since we always have $S \cup a S \subseteq S+a S$ for any subgroup $S$, we see that $F$ is $T \cup-T$-rigid.

Example 7.8. It is well-known that if $K \longrightarrow L$ is a field extension and if $T$ is a usual ordering of $L$, then $S=K \cap T$ is a usual ordering of $K$. This need not hold for $C(\emptyset)$-orderings nor for $S(\emptyset)$-orderings. Consider for example $L=K(\sqrt{\dot{K}})$ and assume that $L$ is equipped with some $C_{\emptyset}$-ordering $T$. Since $\dot{L}^{2} \cap K=\dot{K}$ and $\dot{L}^{2} \subseteq T$, we also have $T \cap K=\dot{K}$ : the $C_{\emptyset}$-ordering $T$ "vanishes" under the restriction. This happens in particular if $K$ is the finite field $\mathbb{F}_{q}$ with an odd number $q$ of elements. With $L=\mathbb{F}_{q^{2}}, \dot{L}^{2}$ is a $C_{\emptyset}$-ordering. Observe that this cannot happen when $T$ is an $S(\emptyset)$-ordering in an extension $L$ of $K$ : since -1 is not in $T$, it cannot be in $S=T \cap K$, and $S$ cannot be the trivial index 1 subgroup. But $S(\emptyset)$-orderings are subject to another pathology of their
own: it may happen that the restriction of an $S(\emptyset)$-ordering is a $C_{2}$-ordering. (Observe that this cannot happen with $C(\emptyset)$-orderings.) Take for example $K=\mathbb{Q}, L=K(\sqrt{10})$, and denote by $N$ the norm map from $L$ down to $K$. Let $\alpha$ be the ordering of $L$ containing $\sqrt{10}$. Let $v$ be the discrete rank 1 valuation on $\mathbb{Q}$ associated to the prime 3. Define $T:=\left\{h \in \dot{L} \mid(-1)^{v(N(h))} h \in \alpha\right\}$. Then $-1 \notin T$ and $T$ is a subgroup containing $\dot{K}^{2}$, of index 2 in $\dot{K}$ (if $x \notin T,-x \in T$ ). It is not a usual ordering, since $-4-\sqrt{10}$ is negative at the two orderings of $L$ but belongs to $T$, as its norm 6 has an odd 3 -valuation. Thus it must be an $S(\emptyset)$-ordering. Since $N(f)=f^{2}$ has an even valuation when $f \in K$, we see that $S:=T \cap K$ is the usual ordering of $\mathbb{Q}$.
The proof of the next proposition is nearly identical with the proof of Proposition 7.6. Therefore in the proof below, we merely indicate the key points of the proof. For the definition of a fan preordering, see [L2, Section 5].
Proposition 7.9. A subgroup $T$ of $\dot{F}$ containing $\dot{F}^{2}$ is a $D(I)$-ordering if and only if the following three conditions hold.
(1) $-1 \notin T$,
(2) $T+T=T$,
(3) $F$ is $T$-rigid, and
(4) $\dot{F} / T \cong \coprod_{i \in I \cup\{x\}}\left(C_{2}\right)_{i}$.

In particular a subgroup $T$ is a $D(I)$-ordering for some index set $I$, if and only if it is a fan, and this happens if and only if $T$ is a rigid ordering of infinite level.
Proof. Assume that $T$ is a $P_{D(I)}$-ordering. Then $D(I)=G_{1} \rtimes C_{2}$ where $G_{1}=$ $\prod_{i}\left(C_{4}\right)_{i}$ and $C_{2}=\langle\tau\rangle$. Further, all elements in $\tau G_{1}$ are involutions not in $\Phi(D(I))$. Therefore we see that $T$ is the intersection of the orderings $P_{\langle\gamma\rangle}, \gamma \in$ $\tau G_{1}$. Hence $T$ is a preordering and conditions (1) and (2) follow. Condition (4) follows from Kummer theory. By Proposition $7.2,-1 \in P_{G_{1}}$, hence $P_{G_{1}}=$ $T \cup-T$ and $F$ is $P_{G_{1}}$-rigid. Since $T$ is a preordering, this implies condition (3). Conversely, if $H$ is an essential subgroup of $\mathcal{G}_{F}$ such that $T=P_{H}$ and $T$ satisfies conditions (1), (2), (3), and (4), one can write $H$ as a topological group generated by $G_{1}$ and $\tau$ where $P_{G_{1}}=T \cup-T$ and $P_{\langle\tau\rangle}$ is a $C_{2}$-ordering of $F$. Using Proposition 7.2 we see that $G_{1}=\prod_{i}\left(C_{4}\right)_{i}$ and using the restrictions of the elements $\sigma^{2}[\sigma, \tau], \sigma \in G_{1}$, on $C_{4}^{a}$ and $D^{a, b}$ extensions, we check that $\sigma^{2}[\sigma, \tau]=1$ for all $\sigma \in G_{1}$. This forces $H \cong G_{1} \rtimes\langle\tau\rangle$ with action $\tau^{-1} \sigma \tau=\sigma^{-1}$ for each $\sigma \in G_{1}$. Hence $H \cong D(I)$ as required.
It is known that conditions (1), (2), and (3) characterize fans [L2, Theorem 5.5], and by Proposition 3.3 we see that they are rigid orderings of infinite level.
To conclude the section we may summarize the results with the following
Theorem 7.10. Rigid orderings are exactly $C(I)-, S(I)-$ or $D(I)$-orderings for some (possibly empty) index set $I$.
Proof. This is a straightforward application of Proposition 3.3, Proposition 7.2, Corollary 7.7 and Proposition 7.9.

## §8. Construction of closures for rigid orderings

In this section we employ valuation-theoretic techniques to construct closures for
$C(I)$-, $S(I)$ - and $D(I)$-orderings. From the preceding section, we know that both $C(I)$ - and $S(I)$-orderings are $T$-rigid. Then for such an ordering we will be able to use results of Arason, Elman, Jacob [AEJ], Efrat [Ef] and Ware [Wa] to associate a valuation to $T$. For $D(I)$-orderings, it is the "Fan Trivialization Theorem" of Bröcker [Br, Theorem 2.7] that will be used. Since it is well known (see $[\mathrm{Ri}]$ ) that for each algebraic extension $K / F$ we can extend any valuation $v$ on $F$ to a valuation $w$ on $K$, we can then use this to extend $S(I)$ - or $D(I)$-orderings, and in most cases also $C(I)$-orderings, from $F$ to $F(\sqrt{t}), t \in T$. This will allow us to prove the existence of $S(I)$ - and $D(I)$-closures, and in most cases also $C(I)$-closures.
For the reader's convenience we define here some of the valuation-theoretic notation we will be using below. For more detailed information, we refer the reader to $[\mathrm{End}]$ and $[\mathrm{Ri}]$ as well as $[\mathrm{AEJ}],[\mathrm{Wa}]$ and $[\mathrm{Br}]$.
Let $v: F \rightarrow \Gamma \cup\{\infty\}$ be a valuation on the field $F$, where $\Gamma$ is some linearly ordered abelian group. Then we set $A_{v}$ to be the valuation subring of $F, M_{v}$ to be the unique maximal ideal of $A_{v}$ (consisting of those elements $f \in F$ such that $v(f)>0$ ), and $U_{v}$ to be the group of invertible elements of $A_{v}$. We say $T$ is compatible with $v$ (or $A_{v}$ ) if $1+M_{v} \subseteq T$. We denote the residue field $A_{v} / M_{v}$ by $F_{v}$, and we set $\pi_{v}: A_{v} \rightarrow F_{v}$ to denote the canonical epimorphism from $A_{v}$ onto $F_{v}$.
The strategy of the proof is as follows: It is easy to reduce the problem of constructing $H$-closures to the problem of extending a given $H$-ordering $T$ of a field $F$ to an $H$-ordering $T^{\prime}$ of any quadratic extension $L=F(\sqrt{t}), t \in T$, such that $T^{\prime} \cap F=T$. (Here $H \cong C(I), S(I)$, or $D(I)$.) In order to extend $T$ in this manner, we first find a suitable $T$-compatible valuation $v$ on $F$ and then extend $v$ to a valuation $w$ on $L$. We then extend the induced ordering $\bar{T}$ of the residue field $F_{v}$ to $\hat{T}$ on the residue field $L_{w}$ of $L$ with respect to the valuation $w$. Finally we lift the ordering $\hat{T}$ from the residue field $L_{w}$ to an ordering $\tilde{T}$ on $L$, and then show that $\tilde{T}$ is the desired extension of $T$ from $F$ to $L$.
Suppose first that we are given some $S(I)$-ordering $T$ of $F$. In this case, $T$ is "not exceptional" in the sense of [AEJ, Definition 2.15]. Thus we can apply [AEJ, Theorem 2.16] to obtain the following.

Proposition 8.1. Let $T$ be any $S(I)$-ordering of $F$. Then there exists a $T$ compatible nondyadic valuation $v$ of $F$ such that $U_{v} T=T \cup-T$. The set $\bar{T}:=\pi_{v}\left(T \cap U_{v}\right)$ is an $S(\emptyset)$-ordering of $F_{v}$.

Proof. By [AEJ, Theorem 2.16], we have a $T$-compatible valuation $v$ such that $U_{v} T=T \cup-T$. The last statement of the proposition follows from this. Indeed we have

$$
\frac{U_{v}}{U_{v} \cap T} \cong \frac{U_{v} T}{T} \cong \frac{T \cup-T}{T}
$$

Since $-1 \notin T$ we see that $F_{v}=\bar{T} \cup-\bar{T}$ and $-1 \notin \bar{T}$. Therefore $\bar{T}$ has index 2 in $\dot{F}_{v}$.
Since $T$ is an $S(I)$-ordering on $F$, we see that there exist elements $t_{1}, t_{2}, t_{3} \in T$ such that $t_{1}+t_{2}+t_{3}=0$. Dividing through by that element $t_{i}$ whose value $v\left(t_{i}\right)$ is minimal among the three elements considered (say $t_{1}$ ), we may assume we have

$$
-1=t_{2}+t_{3}, v\left(t_{2}\right), v\left(t_{3}\right) \geq 0
$$

Passing to the residue field we obtain $\overline{t_{1}}+\overline{t_{2}}=-\overline{1}$ in $F_{v}$. Since $-1 \notin \bar{T}$ we see that $\bar{t}_{i} \neq 0, i=2,3$. Thus $-1 \in \bar{T}+\bar{T} \backslash \bar{T}$, and $\bar{T}$ is a $S(\emptyset)$-ordering of $F_{v}$, as claimed.
Observe also that $-1 \notin \bar{T}$ implies $-1 \neq 1$ and char $F_{v} \neq 2$. Thus $v$ is nondyadic.

Next suppose we have a $C(I)$-ordering $T$ of $F$. Then we may apply [Ef, Propositions 2.1 and 2.3 and Theorem 4.1], to yield the following result.
Proposition 8.2. Let $T$ be any $C(I)$-ordering of $F$. Then there exists a $T$ compatible valuation ring $A_{v}$ of $F$ such that $\left[U_{v} T: T\right] \leq 2$ and $\operatorname{dim}_{\mathbb{F}_{2}} \Gamma / 2 \Gamma \geq$ $|I|$, where $\Gamma$ is the associated value group. The set $\bar{T}:=\pi_{v}\left(T \cap U_{v}\right)$ is either $\dot{F}_{v}$ itself or a $C(\emptyset)$-ordering of $F_{v}$.
Proof. Observe again that the last statement claiming that $\bar{T}:=\pi_{v}\left(T \cap U_{v}\right)$ is either $\dot{F}_{v}$ itself or a $C(\emptyset)$-ordering, and also the statement $\operatorname{dim}_{\mathbb{F}_{2}} \Gamma / 2 \Gamma \geq|I|$, are consequences of the first part of the proposition. We have $\frac{U_{v} T}{T} \cong \frac{U_{v}}{U_{v} \cap T}$, so $\left[U_{v}: U_{v} \cap T\right] \leq 2$; hence $U_{v}=U_{v} T$ or $\left[U_{v}: U_{v} \cap T\right]=2$. In the latter case, we see that $\bar{T}=\pi_{v}\left(T \cap U_{v}\right)$ is a $C(\emptyset)$-ordering as $-\overline{1} \in \bar{T}$. Also observe that we have $|I|+1=\operatorname{dim}_{\mathbb{F}_{2}} \frac{\dot{F}}{T}=\operatorname{dim}_{\mathbb{F}_{2}} \frac{\dot{F}}{U_{v} T}+\operatorname{dim}_{\mathbb{F}_{2}} \frac{U_{v} T}{T}$. From the hypothesis $\left[U_{v} T: T\right] \leq 2$ we see that $\operatorname{dim}_{\mathbb{F}_{2}} \frac{U_{v} T}{T} \leq 1$. Hence $\operatorname{dim}_{\mathbb{F}_{2}} \frac{\dot{F}}{U_{v} T} \geq|I|$. Therefore $\operatorname{dim}_{\mathbb{F}_{2}} \Gamma_{v} \geq \operatorname{dim}_{\mathbb{F}_{2}} \frac{\dot{F}}{U_{v} T} \geq|I|$ as claimed.
Proposition 8.3. (Fan Trivialization Theorem [Br, Theorem 2.7]) Let $T$ be any $D(I)$-ordering of $F$. Then there exists a $T$-compatible valuation ring $A_{v}$ of $F$ such that the set $\bar{T}:=\pi_{v}\left(T \cap U_{v}\right)$ is either an ordering of $F_{v}$ or a $D$-ordering of $F_{v}$. (When $\bar{T}$ is an ordering, $T$ is called a valuation fan.) Moreover, the valuation $v$ may be chosen such that $v(T)$ contains no convex subgroups of $v(F)$.

Now suppose that we have an $S(I)$-ordering (respectively $C(I)$-, $D(I)$-ordering) $T$ together with a $T$-compatible valuation $v$ on $F$. Assume $t \in T$, and let $K=F(\sqrt{t})$. Our goal is to find an $S(I)$-ordering (respectively $C(I)$-, $D(I)$ ordering) $T^{\prime}$ of $K$ such that $T^{\prime} \cap F=T$ and $\dot{F} / T \cong \dot{K} / T^{\prime}$ is the isomorphism of multiplicative groups induced by the inclusion $F \hookrightarrow K$. Note that if $T^{\prime} \cap F=$ $T$, then the map $\dot{F} / T \rightarrow \dot{K} / T^{\prime}$ is injective, so we need only worry about surjectivity. Then recall the well-known Krull's Theorem ([Ri, Theorem 5]):

Theorem 8.4. (Krull) Let $F$ be a field and $\tilde{F}$ any overfield of $F$. Any valuation $v$ in $F$ can be extended to a valuation $\tilde{v}$ in $\tilde{F}$.

Thus there exists a valuation $w$ on $K$ which extends $v$. We now make the following convenient reduction.
Lemma 8.5. Assume that $T_{1} \subseteq T_{2}$ are respectively $S\left(I_{1}\right)$ - and $S\left(I_{2}\right)$-orderings of $F$, and let $t \in T_{1} \backslash \dot{F}^{2}$. Let $K=F(\sqrt{t})$. Suppose $T_{1}^{\prime}$ is an extension of $T_{1}$ to an $S\left(I_{1}\right)$-ordering of $K$. Then $T_{2}^{\prime}:=T_{1}^{\prime} T_{2}$ is an $S\left(I_{2}\right)$-ordering of $K$ extending $T_{2}$.
Proof. We first show that $T_{2}^{\prime} \cap F=T_{2}$. By definition, $T_{2} \subseteq T_{2}^{\prime} \cap F$, and if $f \in T_{2}^{\prime} \cap F$ then there exists $t_{1}^{\prime} \in T_{1}^{\prime}, t_{2} \in T_{2}$ such that $f=t_{1}^{\prime} t_{2}$. This implies $t_{1}^{\prime} \in F \cap T_{1}^{\prime}=T_{1} \subseteq T_{2}$, and $f \in T_{2}$. Thus $T_{2}^{\prime} \cap F=T_{2}$.
Let $\varphi_{2}: \dot{F} / T_{2} \rightarrow \dot{K} / T_{2}^{\prime}$ denote the natural homomorphism induced by the inclusion map $F \hookrightarrow K$. Because $T_{2}^{\prime} \cap F=T_{2}$ we see that $\varphi_{2}$ is injective. Consider the following diagram:

Since $\varphi_{1}: \dot{F} / T_{1} \rightarrow \dot{K} / T_{1}^{\prime}$ is bijective and $T_{1}^{\prime} \subseteq T_{2}^{\prime}$, we see that $\varphi_{2}$ is also surjective.
Finally we shall show that $T_{2}^{\prime}$ is an $S\left(I_{2}\right)$-ordering by checking that conditions (a), (b), (c) of Corollary 7.7 hold. Since $T_{2}^{\prime} \cap F=T_{2}$, we see that $-1 \notin T_{2}^{\prime}$. As $-1 \in T_{1}^{\prime}+T_{1}^{\prime} \subseteq T_{2}^{\prime}+T_{2}^{\prime}$, we see that $T_{2}^{\prime}$ satisfies condition (a).
Suppose $s=u+a v \in K$ with $u, v \in T_{2}^{\prime}$ and $a \notin\left(T_{2}^{\prime} \cup-T_{2}^{\prime}\right)$. By definition of $T_{2}^{\prime}$, $u, v$ can be written $u=u_{1}^{\prime} u_{2}, v=v_{1}^{\prime} v_{2}$ with $u_{1}^{\prime}, v_{1}^{\prime} \in\left(T_{1}^{\prime} \cup-T_{1}^{\prime}\right), u_{2}, v_{2} \in T_{2}$. Then $s u_{2}^{-1}=u_{1}^{\prime}+\left(a v_{2} u_{2}^{-1}\right) v_{1}^{\prime}$. Because $a v_{2} u_{2}^{-1} \notin\left(T_{1}^{\prime} \cup-T_{1}^{\prime}\right)$, the $T_{1}^{\prime}$-rigidity of $K$ implies $s u_{2}^{-1} \in T_{1}^{\prime} \cup\left(a v_{2} u_{2}^{-1}\right) T_{1}^{\prime}$, and thus $s \in T_{2}^{\prime} \cup a T_{2}^{\prime}$, giving condition (b).

Finally, to check condition (c), observe that $\dot{K} / T_{2}^{\prime} \cong \dot{F} / T_{2} \cong \coprod_{i \in I_{2} \cup\{x\}}\left(C_{2}\right)_{i}$. Thus $T_{2}^{\prime}$ is an $S\left(I_{2}\right)$-ordering which extends $T_{2}$.
Lemma 8.6. Assume that $T_{1} \subseteq T_{2}$ are respectively $C\left(I_{1}\right)$ - and $C\left(I_{2}\right)$-orderings of $F$, and let $t \in T_{1} \backslash \dot{F}^{2}$. Let $K=F(\sqrt{t})$. Suppose $T_{1}^{\prime}$ is an extension of $T_{1}$ to a $C\left(I_{1}\right)$-ordering of $K$. Then $T_{2}^{\prime}:=T_{1}^{\prime} T_{2}$ is a $C\left(I_{2}\right)$-ordering of $K$ extending $T_{2}$.
Proof. The proof is identical to that of Lemma 8.5, except that one must now check that $-1 \in T_{2}^{\prime}$. Since $T_{2}^{\prime} \cap F=T_{2}$, we see $-1 \in T_{2}^{\prime}$.
Lemma 8.7. Assume that $T_{1} \subseteq T_{2}$ are respectively $D\left(I_{1}\right)$ - and $D\left(I_{2}\right)$-orderings of $F$, and let $t \in T_{1} \backslash \dot{F}^{2}$. Let $K=F(\sqrt{t})$. Suppose $T_{1}^{\prime}$ is an extension of $T_{1}$ to a $D\left(I_{1}\right)$-ordering of $K$. Then $T_{2}^{\prime}:=T_{1}^{\prime} T_{2}$ is a $D\left(I_{2}\right)$-ordering of $K$ extending $T_{2}$.
Proof. Again the proof takes the same arguments as in the proof of Lemma 8.5 to show that $T_{2}^{\prime}$ extends $T_{2}$, that $-1 \notin T_{2}^{\prime}$ and that $K$ is $T_{2}^{\prime}$-rigid. Let us prove
$T_{2}^{\prime}+T_{2}^{\prime}=T_{2}^{\prime}$. Consider $u, v \in T_{2}^{\prime}$ and write them as above, $u=u_{1}^{\prime} u_{2}, v=v_{1}^{\prime} v_{2}$, with $u_{1}^{\prime}, v_{1}^{\prime} \in T_{1}^{\prime}$ and $u_{2}, v_{2} \in T_{2}$. Then $u+v=u_{2}\left(u_{1}^{\prime}+\left(v_{2} u_{2}^{-1}\right) v_{1}^{\prime}\right)$. We know that $-1 \notin T_{2}^{\prime}$, and this implies that $v_{2} u_{2}^{-1} \notin-T_{1}^{\prime}$. If $v_{2} u_{2}^{-1} \in T_{1}^{\prime}$, then $(u+v) u_{2}^{-1} \in T_{1}^{\prime}+T_{1}^{\prime}=T_{1}^{\prime}$ and $u+v \in T_{2}^{\prime}$. The remaining possibility is $v_{2} u_{2}^{-1} \notin T_{1}^{\prime} \cup-T_{1}^{\prime}$, and by $T_{1}^{\prime}$-rigidity of $K$, we have $(u+v) u_{2}^{-1} \in T_{1}^{\prime} \cup\left(v_{2} u_{2}^{-1}\right) T_{1}^{\prime}$ and $u+v \in T_{2}^{\prime}$. Hence condition (2) holds.

We consider the following situation. Assume that $v: F \rightarrow \Gamma_{v} \cup\{\infty\}$ is a valuation on the field $F$, with valuation ring $A_{v}$ and maximal ideal $M_{v}$. Let $F_{v}=A_{v} / M_{v}$ be the residue field, and denote by $\pi_{v}$ the canonical homomorphism of $A_{v}$ onto its quotient ring $F_{v}$.

Lemma 8.8. Assume that $v$ is a valuation on the field $F$ and that $T_{0}$ is an $S\left(I_{0}\right)$-ordering of $\dot{F}_{v}$ for some (possibly empty) set $I_{0}$. Set $T_{1}=\pi_{v}^{-1}\left(T_{0}\right)$. Then the group $T=T_{1} \dot{F}^{2}$ is an $S(I)$-ordering of $F$ with $|I|=\operatorname{dim}_{\mathbb{F}_{2}}\left(\frac{\dot{F}}{T \cup-T}\right)$.
Proof. We need to check that the conditions in Corollary 7.7 hold for T. First, suppose that $-1 \in T$. Then $-1=t_{0} f^{2}$ for some $t_{0} \in T_{1}, f \in \dot{F}$. Hence $f^{2}=\left(-t_{0}\right)^{-1} \in-T_{1} \subseteq U_{v}$, and so $f \in U_{v}$ as well. Passing to the residue field $F_{v}$ and knowing $\dot{F}_{v}{ }^{2} \subseteq T_{0}$ we see $-1=\bar{t}_{0} \bar{f}^{2} \in T_{0}$, which is a contradiction. Thus we must have $-1 \notin T$. Since $-1 \in T_{0}+T_{0}$, we have $-1+m \in T_{1}+T_{1}$ for some $m$ in the maximal ideal of the valuation, and $-1+m \in-T_{1} \subset T$. This shows that the level of $T$ is 2 .
To see that $F$ is $T$-rigid, let $a \in \dot{F} \backslash(T \cup-T), t_{1}, t_{2} \in T$, and consider $b:=$ $t_{1}+t_{2} a$. We consider various possibilities for $v\left(t_{1}\right)$ relative to $v\left(t_{2} a\right)$. First suppose that $v\left(t_{1}\right)=v\left(t_{2} a\right)$. Then $b=t_{1}\left(1+t_{1}^{-1} t_{2} a\right)$, with $u:=t_{1}^{-1} t_{2} a \in U_{v}$. Since $a \notin T \cup-T$, we see that $\pi_{v}(u)=\bar{u} \notin T_{0} \cup-T_{0}$. (Otherwise $u \in \pi_{v}^{-1}\left(T_{0}\right)=$ $T_{1} \subseteq T$ or $u \in-\pi_{v}^{-1}\left(T_{0}\right)=-T_{1} \subseteq-T$ and hence $a \in T \cup-T$, a contradiction.) Since we are assuming $F_{v}$ is $T_{0}$-rigid, we see that $1+\bar{u} \in T_{0} \cup \bar{u} T_{0}$. Hence $1+u \in \pi_{v}^{-1}\left(T_{0} \cup \bar{u} T_{0}\right)=T_{1} \cup u T_{1}$. Thus, rewriting $u=t_{1}^{-1} t_{2} a$ and multiplying through by $t_{1}$, we see

$$
b=t_{1}+t_{2} a \in T_{1} \cup a T_{1} \subseteq T \cup a T
$$

as required. Now assume that $v\left(t_{1}\right) \neq v\left(t_{2} a\right)$. If $v\left(t_{1}\right)<v\left(t_{2} a\right)$, then again let $b=t_{1}(1+u)$, where $u=t_{1}^{-1} t_{2} a$. Now, however, $v(u)>0$, so $1+u \in 1+M_{v} \subseteq$ $T_{1}=\pi_{v}^{-1}\left(T_{0}\right)$, and thus $b \in T$. If $v\left(t_{1}\right)>v\left(t_{2} a\right)$, set $b=a t_{2}\left(1+t_{1} t_{2}^{-1} a^{-1}\right)$. We see $v\left(t_{1} t_{2}^{-1} a^{-1}\right)>0$, and therefore $b \in a T$. In each case $b=t_{1}+a t_{2} \in T \cup a T$ as desired.
It remains to see that $\dot{F} / T \cong \coprod_{i \in I \cup\{x\}}\left(C_{2}\right)_{i}$. This condition follows from the fact that $\dot{F} / T$ is an $\mathbb{F}_{2}$-vector space and that $\operatorname{dim}_{\mathbb{F}_{2}} \dot{F} / T$ is $1+|I|$.
We have the analogue to Lemma 8.8 for the case of $C(I)$-orderings.
Lemma 8.9. Assume that $v$ is a valuation on the field $F$ such that $\left[\Gamma_{v}: 2 \Gamma_{v}\right] \geq$ 2. Let $T_{0}$ be $\dot{F}_{v}$ or a $C\left(I_{0}\right)$-ordering of $F_{v}$ for some (possibly empty) set $I_{0}$.

Set $T_{1}=\pi_{v}^{-1}\left(T_{0}\right)$. Then the group $T=T_{1} \dot{F}^{2}$ is a $C(I)$-ordering of $F$ with $|I|=\operatorname{dim}_{\mathbb{F}_{2}}\left(\frac{\dot{F}}{T}\right)-1$.
Proof. We must check that the conditions of Proposition 7.2 hold for $T$. Clearly if $-1 \in T_{0}$, then $-1 \in T_{1} \subseteq T$. To see that $F$ is $T$-rigid, one applies the same argument as in Lemma 8.8. As in the case for $S(I)$-orderings, $\dot{F} / T$ is clearly an $\mathbb{F}_{2}$-vector space. Since $\left[\Gamma_{v}: 2 \Gamma_{v}\right] \geq 2$, its dimension is strictly positive and thus may be written $\operatorname{dim}_{\mathbb{F}_{2}}(\dot{F} / T)=1+|I|$.

Again, we also have the analogue to Lemma 8.8 for the case of $D(I)$-orderings.
Lemma 8.10. ([Br]) Assume that $v$ is a valuation on the field $F$. Let $T_{0}$ be a fan of $\dot{F}_{v}$. Set $T_{1}=\pi_{v}^{-1}\left(T_{0}\right)$. Then the group $T=T_{1} \dot{F}^{2}$ is a fan (i.e. a $D(I)$-ordering) of $F$.
We now formulate the key results in this section.
Theorem 8.11. Let $T$ be any $S(I)$-ordering of $F$ and let $L=F(\sqrt{t}), t \in$ $T$. Then there exists an $S(I)$-ordering $T^{\prime}$ on $L$ such that $\left(L, T^{\prime}\right)$ is an $S(I)$ extension of $(F, T)$.

Proof. From Proposition 8.1, we see that there exists a nondyadic $T$-compatible valuation ring $A_{v}$ in $F$ such that $U_{v} T=T \cup-T$ and that $\bar{T}:=\pi_{v}\left(U_{v} \cap T\right)$ is an $S(\emptyset)$-ordering of $F_{v}$. As $\pi_{v}^{-1}(\bar{T})=\left(U_{v} \cap T\right)\left(1+M_{v}\right)$ and because $\left(1+M_{v}\right) \subseteq T$, one has $T_{1}:=\pi_{v}^{-1}(\bar{T}) \dot{F}^{2} \subseteq T$. By Lemma 8.8, we see that $T_{1}$ is an $S(J)$ ordering in $F$ for a suitable set $J$.
Let $w$ be any valuation of $L$ which extends $v$. Let $L_{w}$ denote its residue field, and $\Gamma_{v}, \Gamma_{w}$ denote the valuation groups of $v$ and $w$. We may assume $\Gamma_{v} \subseteq \Gamma_{w}$, and we set $e=\left[\Gamma_{w}: \Gamma_{v}\right]$, the ramification degree of $w$ with respect to $v$, and $f=\left[L_{w}: F_{v}\right]$, the residue class degree of $w$ with respect to $v$. It is well known that ef $\leq[L: F]=2$ and in particular we have $f=\left[L_{w}: F_{v}\right] \leq 2$. More precisely, one has $L_{w}=F_{v}\left(\sqrt{\pi_{v}\left(u_{0}\right)}\right)$ with $u_{0}=1$ if $f=1$, and $u_{0} / t \in \dot{F}^{2}$ if $f=2$. By Proposition 5.6 and Remark $5.5, C_{4}$-orderings are known to admit $C_{4}$-closures of the same level, and as $\pi_{v}\left(u_{0}\right) \in \bar{T}$, the $S(\emptyset)$-ordering $\bar{T}$ admits an $S(\emptyset)$-extension $\tilde{T}$ to $F_{v}\left(\sqrt{\pi_{v}\left(u_{0}\right)}\right)=L_{w}$. Calling $T_{2}=\pi_{w}^{-1}(\tilde{T}) L^{2}$, Lemma 8.8 implies that $T_{2}$ is an $S(K)$-ordering of $L$ for a suitable set $K$.
Let us first show that $T_{1}=T_{2} \cap F$. By definition of $T_{1}$, an element $s \in T_{1}$ has the same square class as an element $u \in U_{v}$ such that $\pi_{v}(u) \in \bar{T} \subseteq \tilde{T}$. This implies that $\pi_{w}(u) \in \tilde{T}$, and thus $u$ and $s$ are in $T_{2}$. This shows $T_{1} \subseteq T_{2} \cap F$. For the reverse inclusion, we state the following claim:

Claim. With notation as above, one has $\dot{L}=U_{w} \dot{F} \cup \sqrt{t} U_{w} \dot{F}$.
Proof. We know that $e \leq 2$. If $e=1$, then $\dot{L}=\dot{F} U_{w}$ and we are done. If $e=2$, then $f=1$ and we may show that $w(\sqrt{t}) \notin \Gamma_{v}$. Otherwise $\sqrt{t}=x u$ with $x \in F$ and $u \in U_{w}$, and denoting by $\sigma$ the nontrivial element of the Galois group $\operatorname{Gal}(L / F)$, we know that $\frac{\sigma(\sqrt{t})}{\sqrt{t}}=-1$ and thus $\pi_{w}\left(\frac{\sigma(\sqrt{t})}{\sqrt{t}}\right)=\pi_{w}\left(\frac{\sigma(u)}{u}\right)=-1$. Since $f=1, L_{w}=F_{v}$, and so $\pi_{w}\left(\frac{\sigma(u)}{u}\right)$ must also be 1 . Since the valuation
$v$ is not dyadic, this would be a contradiction. Thus we see that since $\Gamma_{w} \cong$ $\dot{L} / U_{w}, \Gamma_{v} \cong \dot{F} / U_{v}$, and $\left[\Gamma_{w}: \Gamma_{v}\right]=2$, the factor group $\dot{L} / U_{w} \dot{F}$ is $\{1, \sqrt{t}\}$, and we can write $\dot{L}=U_{w} \dot{F} \cup \sqrt{t} U_{w} \dot{F}$.
We now finish the proof of the theorem. If $\alpha \in T_{2} \cap F$, we may write $\alpha=u \lambda^{2}$ with $u \in \pi_{w}^{-1}(\tilde{T}), \lambda \in \dot{L}$, and writing $\lambda=\sqrt{t}^{\eta} u_{1} g$ with $u_{1} \in U_{w}, g \in \dot{F}, \eta=0$ or 1, this yields $\alpha=u u_{1}^{2} t^{\eta} g^{2}$. Since $t^{\eta} g^{2} \in T_{1}$, we may assume $\alpha=u u_{1}^{2}$. Then $\pi_{v}(\alpha)=\pi_{w}(\alpha) \in \tilde{T} \cap F_{v}=\bar{T}$ and $\alpha \in T_{1}$. This proves $T_{1}=T_{2} \cap F$.
We define a new subgroup $T_{2}^{\prime}$ of $\dot{L}$ as follows.
(1) If $\sqrt{t} \in\left(T_{2} \cup-T_{2}\right)$, set $T_{2}^{\prime}=T_{2}$.
(2) If $\sqrt{t} \notin\left(T_{2} \cup-T_{2}\right)$ and $\left[\Gamma_{w}: \Gamma_{v}\right]=1$, again set $T_{2}^{\prime}=T_{2}$.
(3) If $\sqrt{t} \notin\left(T_{2} \cup-T_{2}\right)$ and $\left[\Gamma_{w}: \Gamma_{v}\right]=2$, set $T_{2}^{\prime}=T_{2} \cup \sqrt{t} T_{2}$.

Then again $T_{1}=T_{2}^{\prime} \cap F$, the only thing to prove being that in the third case, $\sqrt{t} T_{2} \cap F \subseteq T_{1}$. But if $\alpha \in \sqrt{t} T_{2} \cap F$ we have $\alpha=\sqrt{t} u g^{2}$ with $u \in U_{w}, g \in \dot{F}$ and this implies $w(\sqrt{t}) \in \Gamma_{v}$, contradicting $\left[\Gamma_{w}: \Gamma_{v}\right]=2$. This shows that $\sqrt{t} T_{2} \cap F=\emptyset$ in the third case.
Since $T_{2}$ is an $S(K)$-ordering, it is easy to check that conditions (1)-(3) of Proposition 7.6 hold for $T_{2}^{\prime}$ and to see that $T_{2}^{\prime}$ is also an $S\left(K^{\prime}\right)$-ordering for a suitable set $K^{\prime}$.
We want to show that the injection $\dot{F} / T_{1} \longrightarrow \dot{L} / T_{2}^{\prime}$ is also surjective, which reduces to showing that $\dot{L}=T_{2}^{\prime} \dot{F}$. We already know $\dot{L}=U_{w} \dot{F} \cup \sqrt{t} U_{w} \dot{F}$, and by Lemma 8.1, $U_{w} \subseteq T_{2} \cup-T_{2}$. This gives us $U_{w} \dot{F} \subseteq T_{2} \dot{F} \subseteq T_{2}^{\prime} \dot{F}$. In cases (1) and (3), one has $\sqrt{t} \in T_{2}^{\prime} \cup-T_{2}^{\prime}$, and so $\dot{L} \subseteq T_{2}^{\prime} \dot{F}$. In case (2), there exists $x_{0} \in \dot{F}$ such that $\sqrt{t} x_{0} \in U_{w} \subseteq T_{2} \dot{F}$. So $\sqrt{t} \in T_{2} \dot{F}$, finishing the proof that $\dot{F} / T_{1} \longrightarrow \dot{L} / T_{2}^{\prime}$ is an isomorphism.
We have proved so far that $\left(L, T_{2}^{\prime}\right)$ is an $S(J)$-extension of $\left(F, T_{1}\right)$, and that $T_{1}$ is contained in the $S(I)$-ordering $T$. We may then apply Lemma 8.5 to show that $\left(L, T_{1} T_{2}^{\prime}\right)$ is an $S(I)$-extension of $(F, T)$, and the theorem is proved.
Corollary 8.12. An $S(I)$-ordered field $(F, T)$ admits an $S(I)$-closure.
Proof. Let $\mathcal{S}$ be the set of extensions $(L, S)$ of $(F, T)$ inside $F(2)$ such that $S$ is an $S(I)$-ordering on $L$. Then by a Zorn's Lemma argument $\mathcal{S}$ has a maximal element ( $K, T_{0}$ ) with $\dot{K} / T_{0} \cong \dot{F} / T, T=T_{0} \cap F$, and $T_{0}$ is an $S(I)$-ordering on $K$. We are done by Corollary 4.3 if we can show $T_{0}=\dot{K}^{2}$. If not, choose $t \in T_{0} \backslash \dot{K}^{2}$. Then by Theorem 8.11 we can extend $T_{0}$ to an $S(I)$-ordering on $K(\sqrt{t})$, contradicting the maximality of $\left(K, T_{0}\right)$.
Corollary 8.12 can be reformulated in the language of Galois theory as in the following corollary, which tells us that a certain family of subgroups of $G_{F}:=\operatorname{Gal}(F(2) / F)$ occurs whenever $G_{F}$ contains certain subquotients of $G_{F}$. Observe that in Corollary 8.13 we do not specify the action of the outer factor $\mathbb{Z}_{2}$ on the normal subgroup $\left(\mathbb{Z}_{2}\right)^{I}$ as this action depends upon a subtler analysis of the roots of unity belonging to the fields under consideration.
Corollary 8.13. Let $F$ be a field of characteristic $\neq 2$. Suppose that we have a tower of field extensions $F \subset N_{1} \subset N_{2} \subset N_{1}^{(3)} \subset F(2)$, such that
$\operatorname{Gal}\left(N_{1}^{(3)} / N_{2}\right) \cong\left(C_{4}\right)^{I} \rtimes C_{4}$ for I some nonempty set. Then $G_{F}=\operatorname{Gal}(F(2) / F)$ contains the closed subgroup $\left(\mathbb{Z}_{2}\right)^{I} \rtimes \mathbb{Z}_{2}$.
Proof. Let $F \subset N_{1} \subset N_{2} \subset N_{1}^{(3)} \subset F(2)$ be a tower of field extensions, where $N_{1}^{(3)} / N_{2}$ is a Galois extension and $\operatorname{Gal}\left(\frac{N_{1}^{(3)}}{N_{2}}\right) \cong\left(C_{4}\right)^{I} \rtimes C_{4}$ for $I$ some nonempty set. Set $T=\left\{t \in \dot{N}_{1} \mid(\sqrt{t})^{\sigma}=\sqrt{t}\right.$ for each $\left.\sigma \in \operatorname{Gal}\left(N_{1}^{(3)} / N_{2}\right)\right\}$. From Definition 7.1 we see that $T$ is an $S(I)$-ordering of $N_{1}$. From Corollary 8.12 it follows that there exists a field extension $N$ of $N_{1}$ such that $\dot{N}^{2}$ is an $S(I)$ ordering of $N$ and $\dot{N}^{2} \cap N_{1}=T$. Then Proposition 8.1 implies the existence of an $\dot{N}^{2}$-compatible valuation ring $A_{v}$ of $N$ such that $U_{v} \dot{N}^{2}=\dot{N}^{2} \cup-\dot{N}^{2}$.
It is well known that an $\dot{N}^{2}$-compatible valuation $v$ on $N$ is 2-henselian. Moreover $N$ is a rigid field (and is $S(I)$-closed). In Proposition 8.1 we observed that $v$ is a nondyadic valuation (i.e., char $F_{v} \neq 2$ ) and in this case it follows from basic valuation theory (see e.g. [End, §20]) that we have a split short exact sequence

$$
1 \longrightarrow I_{v} \longrightarrow G_{N}(2) \longrightarrow G_{N_{v}}(2) \longrightarrow 1
$$

where $I_{v}$ is the inertia subgroup of $G_{N}(2):=\operatorname{Gal}(N(2) / N)=\operatorname{Gal}(F(2) / N)$ and $N_{v}$ is the residue field of $v$. Moreover it is well known that $I_{v}$ is an abelian group. (See e.g. [EnKo].)
Because $\dot{N}^{2}$ is an $S(I)$-ordering of $N$ we see that $s(N)=2$. In particular $N$ is not a formally real field, and so $G_{N}(2)$ is a torsion-free group. (See [Be].) Therefore using Pontrjagin's duality and the well-known structure of abelian divisible groups, we see that $I_{v} \cong\left(\mathbb{Z}_{2}\right)^{J}$ for some set $J$. (See e.g. [RZ, §4.3, Theorem 4.3.3].)
Because $\dot{N}^{2}$ is compatible with $v$ and

$$
\frac{U_{v}}{U_{v} \cap \dot{N}^{2}} \cong \frac{\dot{N}^{2} \cup-\dot{N}^{2}}{\dot{N}^{2}}
$$

we see that $\left|\dot{N}_{v} / \dot{N}_{v}^{2}\right|=2$. Hence $G_{N_{v}}(2) \cong \mathbb{Z}_{2}$. Since $\dot{N}^{2}$ is an $S(I)$-ordering of $N$, it follows that the cardinality of $I$ is the same as the cardinality of $J$. Hence $I_{v} \cong\left(\mathbb{Z}_{2}\right)^{I}$. Since the Galois group $G_{N}(2)=I_{v} \rtimes \mathbb{Z}_{2}$ is a closed subgroup of $G_{F}$, the proof is completed.

In the case of $C(I)$-orderings, we cannot always find a closure. The problem arises from the fact that the valuation whose existence is guaranteed by Proposition 8.2 may be dyadic, and thus the appropriate modification of Theorem 8.11 will not go through. For $S(I)$ - and $D(I)$-orderings we do not have this problem, as the valuation in question will be nondyadic. Example 8.14 below constructs a $C(1)$-ordered field which we show in Proposition 8.15 does not admit a $C(1)$-closure.
Example 8.14. Recall that a field $K$ of characteristic 2 is called perfect if $K^{2}=K$. S. MacLane has shown that for any field $K$ of characteristic 2, there exists a field $F$ of characteristic 0 with a valuation $v: F \rightarrow \mathbb{Z} \cup\{\infty\}$ such that
$F_{v} \cong K$ ([Mac, Theorem 2]. For some more general theorems on valued fields with prescribed residue fields, see [Ri, Chapter I]). Then let $F$ be such a field where $F_{v}=K$ is a field of characteristic 2 which is not perfect. Let $T_{0}$ be a multiplicative subgroup of $\dot{K}$ of index 2 in $\dot{K}$ such that $\dot{K}^{2} \subsetneq T_{0} \subsetneq \dot{K}$. Let $T=\dot{F}^{2} \pi_{v}^{-1}\left(T_{0}\right)$, a subgroup of $\dot{F}$. Here $\pi_{v}$ is the residue map $U_{v} \longrightarrow \dot{K}$. Then $|\dot{F} / T|=4$, and one can choose as representatives of the factor group $\dot{F} / T$ the elements $1, u, \rho, \rho u$ where $v(\rho)=1, u \in U_{v}$, and $\pi_{v}(u) \notin T_{0}$.
We claim that $F$ is $T$-rigid. Since any element in $\rho T$ or in $\rho u T$ lies outside of $U_{v} T$, we see that all elements of $\rho T \cup \rho u T$ are $T$-rigid. (See [AEJ, Proposition 1.5.]) Consider an element $\alpha=t_{1}+t_{2} u \in T+u T$, with $t_{1}, t_{2} \in \dot{F}$. Then $\alpha=t_{2}\left(t_{1} t_{2}^{-1}+u\right)$, so it is enough to show $t_{1} t_{2}^{-1}+u \in T \cup u T$. Thus we may restrict our attention to elements which can be written as $t f^{2}+u$, where $t \in \pi_{v}^{-1}\left(T_{0}\right), f \in \dot{F}$. If $v(f)=0$, then $t f^{2}+u \in U_{v} \subseteq T \cup u T$. If $v(f)>0$, then $t f^{2}+u=u\left(1+t f^{2} u^{-1}\right) \in u T$. Finally, if $v(f)<0$, then $t f^{2}+u=t f^{2}\left(1+u f^{-2} t^{-1}\right) \in T$. Thus $F$ is $T$-rigid.
Since $-1 \in T_{0}$, we have $-1 \in T$, and $T$ is a $C(1)$-ordering of $F$. Observe that $T \neq \dot{F}^{2}$ and $(F, T)$ is not $C(1)$-closed.

Proposition 8.15. The $C(1)$-ordered field $(F, T)$ does not admit a $C(1)$ closure.

Proof. Recall that a valuation $\nu$ on a field $L$ is said to be $T$-coarse if $\nu(T)$ contains no nontrivial convex subgroups of the valuation group $\Gamma_{\nu}$ of $\nu$. Suppose that $F \subsetneq N \subsetneq F(2), \dot{N}^{2} \cap F=T$, and $\dot{N}^{2}$ is a $C(1)$-ordering of $N$. Then applying [AEJ, Corollary 2.1.7] or [Wa, Theorem 2.16], we see that there exists a $\dot{N}^{2}$-compatible valuation $w$ on $N$ such that $\left[U_{w} \dot{N}^{2}: \dot{N}^{2}\right] \leq 2$. This means that $\left|U_{w} / U_{w} \cap \dot{N}^{2}\right| \leq 2$. We may further choose $w$ to be the unique finest $N^{2}$ coarse $N^{2}$-compatible valuation on $N$ (see [AEJ, Theorem 3.8]). Consider $z:=$ the restriction of the valuation $w$ to $F$. First observe that $z$ is a $T$-compatible valuation on $F$. Indeed, from $M_{w} \cap F=M_{z}$ we get $\left(1+M_{w}\right) \cap F=1+M_{z}$. Thus we have

$$
1+M_{z}=\left(1+M_{w}\right) \cap F \subseteq \dot{N}^{2} \cap F=T
$$

Let $\Delta$ be the maximal convex subgroup of $\Gamma_{z}$ contained in $z(T)$. Then set $y$ to be the composite valuation

$$
y: \dot{F} \xrightarrow{z} \Gamma_{z} \xrightarrow{\rho} \Gamma_{z} / \Delta,
$$

where the last map $\rho: \Gamma_{z} \rightarrow \Gamma_{z} / \Delta$ is the natural projection. Then, following the notation of [AEJ, Definition 2.2], the valuation ring $A_{y}=O_{F}\left(U_{z} T, T\right)$, and $y(T)$ contains no nontrivial convex subgroups of the value group $\Gamma_{y}=\Gamma_{z} / \Delta$ ([AEJ, Lemma 3.1 and Proposition 3.2]), so $y$ is $T$-coarse. Observe that $y$ is also $T$-compatible. However, since $\Gamma_{v}=\mathbb{Z}$ and $v(T)=2 \mathbb{Z} \neq \mathbb{Z}$, the valuation $v$ is also $T$-coarse. Hence, by [AEJ, Corollary 3.7], we see that the valuations $v$ and $y$ are comparable. Since $A_{v}$ is a maximal proper subring of $F$ (because $\Gamma_{v}=\mathbb{Z}$ ), we see that $A_{v} \supseteq A_{y} \supseteq A_{z}$. However, since $M_{z} \supseteq M_{y} \supseteq M_{v}$ and $2 \in M_{v}$, we
see that both valuations $y$ and $z$ are dyadic. Since $F_{z} \subseteq F_{w}$, it follows that $w$ is also dyadic. But from [AEJ, Theorem 3.8 and Lemma 4.4], it follows that $w$ cannot be a dyadic valuation. Indeed, $\left[D_{N}\left\langle 1,-n^{2}\right\rangle \dot{N}^{2}: \dot{N}^{2}\right]=4>2$ for all $n \in \dot{N}$. Thus we have a contradiction, and there can be no $C(1)$-closure of $(F, T)$.

Remark 8.16. Example 8.14 is analogous to Proposition 4.5. What makes this example striking when compared to Proposition 4.5 is that here we have $|\dot{F} / T|=4<\infty$, but in Proposition $4.5|\dot{F} / T|=\infty$. Although this example is a relatively simple consequence of the work in [AEJ], it seems to be the first example where the Witt ring of a field with finitely many square classes is realizable as a "Witt ring of $T$-forms over some field $F$ ", but it is not realizable as an actual Witt ring of any field extension $K$ of $F$. We make this last comment more precise.
First observe that, analogous to the definition of reduced Witt rings of fields, one may define $W_{T}(F)$ for any subgroup $T$ of $\dot{F}$ which contains all nonzero squares in $F$. One possible definition is as follows: (See also [La2, Corollary 1.27] and [Sc, Chapter 2, § 9].)
Let $\mathbb{Z}[\dot{F} / T]$ be the group ring of $\dot{F} / T$ with coefficients in $\mathbb{Z}$. Let $J$ be the ideal of $\mathbb{Z}[\dot{F} / T]$ generated by
(1) $[T]+[-T]$,
(2) $[a T]+[b T]-[(a+b) T]-[a b(a+b) T],(a, b, a+b \in \dot{F})$,
(3) $[a T][b T]-[a b T],(a, b \in \dot{F})$.

Then we set $W_{T}(F)=\mathbb{Z}[\dot{F} / T] / J$.
A systematic study of $W_{T}(F)$ for $H$-orderings $T$ of $F$ is very desirable, but it is not pursued in this particular paper. Here we just point out that if $T$ is any $C(1)$-ordering of $F$ then $W_{T}(F) \cong W\left(\mathbb{Q}_{p}\right)$, where $p$ is any prime such that $p \equiv 1(\bmod 4)$, and $\mathbb{Q}_{p}$ is the field of $p$-adic numbers.
Since $T$ is a $C(1)$-ordering in $\dot{F}$ and $\dot{\mathbb{Q}}_{p}^{2}$ is a $C(1)$-ordering in $\mathbb{Q}_{p}$ (see Proposition 7.2 and [L1, Chapter 6]), we see that there exists a group homomorphism $\varphi: \dot{F} / T \longrightarrow \dot{\mathbb{Q}}_{p} / \dot{\mathbb{Q}}_{p}^{2}$ such that $\varphi$ takes any relation in the form (1), (2) or (3) above again to a relation of the same type. Using the same argument for $\varphi^{-1}$ rather than $\varphi$, we see that $\varphi$ indeed induces an isomorphism $\tilde{\varphi}: W_{T}(F) \cong W\left(\mathbb{Q}_{p}\right)$.

Similar to Proposition 4.12, we have the following proposition.
Proposition 8.17. Let $(F, T)$ be the field $F$ with $C(1)$-ordering $T$ constructed in Example 8.14 above. Then there is no field extension $K / F$ with $C(1)-$ ordering $\dot{K}^{2}$ which is a $T$-extension of $(F, T)$. (Equivalently, $W_{T}(F)$ cannot be realized as $W(K)$ for any field extension $K$ of $F$.)
Proof. Suppose to the contrary that there exists a field extension $K / F$ such that $\dot{K}^{2}$ is a $C(1)$-ordering of $K$ and $\left(\dot{K}, \dot{K}^{2}\right)$ is a $T$-extension of $(F, T)$. Assume that both $K$ and a quadratic closure $F(2)$ of $F$ are contained in some
common overfield so that we can consider the field $L=K \cap F(2)$. The natural isomorphism $\psi: \dot{F} / T \longrightarrow \dot{K} / \dot{K}^{2}$ factors through $\theta: \dot{F} / T \longrightarrow \dot{L} /\left(\dot{K}^{2} \cap L\right)$. Because $\psi$ is injective, so is $\theta$. Observe that $\theta$ is also surjective. Indeed since $\psi$ is surjective, we see that for each $l \in \dot{L}$ there exists an element $f \in \dot{F}$ such that $l f^{-1} \in \dot{K}^{2} \cap L$. Thus we see that $\left(L, \dot{K}^{2} \cap L\right)$ is a $T$-extension of $(F, T)$.
We claim that $\left(\dot{L}, \dot{K}^{2} \cap L\right)$ is a $C(1)$-closure of $(F, \dot{T})$. Observe that $\dot{K}^{2} \cap L=\dot{L}^{2}$. Indeed if $k^{2} \in L, k \in \dot{K}$ then $k \in \dot{K} \cap F(2)=\dot{L}$. Since $\dot{L}^{2} \subset \dot{K}^{2} \cap L$ is obvious, we see that $\dot{K}^{2} \cap L=\dot{L}^{2}$. In order to conclude the proof, it is enough to show that $\dot{L}^{2}$ is a $C(1)$-ordering in $\dot{L}$. Because $\sqrt{-1} \in \dot{K}$ we see that $\sqrt{-1} \in \dot{L}$ as well, and $-1 \in \dot{L}^{2}$. From the isomorphism $\theta: \dot{F} / T \longrightarrow \dot{L} / \dot{L}^{2}$ we see that $\dot{L} / \dot{L}^{2}=C_{2} \oplus C_{2}$. By Proposition 7.2 it remains only to show that $L$ is $\dot{L}^{2}$-rigid. Consider an element $a \in \dot{L} \backslash \dot{L}^{2}$. For any $l \in \dot{L}$ we have $l^{2}+a \in \dot{K}^{2} \cup a \dot{K}^{2}$ because $\dot{K}$ is $\dot{K}^{2}$-rigid and $\dot{L}^{2}=\dot{K}^{2} \cap L$. Hence $l^{2}+a \in\left(\dot{K}^{2} \cap L\right) \cup\left(a \dot{K}^{2} \cap L\right)$. Finally since $\dot{K}^{2} \cap L=\dot{L}^{2}$ and $a \dot{K}^{2} \cap L=a \dot{L}^{2}$ we see that $\dot{L}$ is $\dot{L}^{2}$-rigid.
Theorem 8.18. A $C(I)$-ordered field $(F, T)$ possessing a nondyadic $T$ compatible valuation ring $A_{v}$ as in Proposition 8.2 admits a $C(I)$-closure.
Proof. The proof is essentially the same as the proof of Theorem 8.11 and Corollary 8.12, and we will follow the same plan and the same notation. Applying Proposition 8.2, we find a valuation $v$ on $F$ such that $\bar{T}:=\pi_{v}\left(U_{v} \cap T\right)$ is either $\dot{F}_{v}$ or a $C$-ordering. By assumption here this valuation is nondyadic. By Lemma 8.9, $T_{1}$ is a $C(J)$-ordering contained in $T$. Taking any valuation $w$ on $L=F(\sqrt{t})$ extending $v$, we extend $\bar{T}$ to $\tilde{T}$ in $L_{w}$. We obtain, by Lemma 8.9, a $C(K)$-ordering $T_{2}$ in $L$. We enlarge it to a $C\left(K^{\prime}\right)$-ordering $T_{2}^{\prime}$, according to the three cases (1), (2), (3), replacing $T_{2} \cup-T_{2}$ by $T_{2}$. The only serious change is in proving that $\dot{L}=T_{2}^{\prime} \dot{F}$. For this it is enough to show that $U_{w} \subseteq T_{2} \dot{F}$, which can be done as follows. If the index $\left[U_{v} T: T\right]=\left[\dot{F}_{v}: \bar{T}\right]$ is 1 , then $\left[\dot{L_{w}}: \tilde{T}\right]=\left[U_{w} T_{2}: T_{2}\right]=1$ and $U_{w} \subseteq T_{2}$. If this index is 2, there exists $a \in U_{v}$ such that $U_{w} \subseteq T_{2} \cup a T_{2} \subseteq T_{2} \dot{F}$. This shows that $\left(L, T_{2}^{\prime}\right)$ is a $C(J)$-extension of $\left(F, T_{1}\right)$, and we apply Lemma 8.5 to show that $\left(L, T_{1} T_{2}^{\prime}\right)$ is a $C(I)$-extension of $(F, T)$. We finish by applying the same argument as in Corollary 8.12.

The following observation about valuations when $F$ contains a real-closed field was pointed out to us by J.-L. Colliot-Thélène. It contains a convenient condition for a valuation $v$ to be nondyadic, and thus it is related to Theorem 8.18.
Example 8.19. Let $v$ be a valuation with value group $\Gamma$, and denote by $U_{v}$ the units of the valuation ring. Suppose there exists an integer $n>1$ such that any $n$-divisible subgroup of $\Gamma$ is trivial. Assume that $F$ contains a real-closed field $R$. Then $R$ is contained in $U_{v}$, and in particular the valuation is nondyadic.
Proof. Assume $F$ contains a real-closed field $R$. If $a \in R$ is positive, for the given integer $n$ there exists $b \in R$ such that $a=b^{n}$, and thus $v(a)=n v(b)$. Thus $v(a)$, being divisible by any power of $n$, must be 0 , and the nonzero elements of $R$ must be units. This implies that the residue field $F_{v}$ contains an isomorphic copy of $R$, and the valuation $v$ cannot be dyadic.

Theorem 8.20. A $D(I)$-ordered field $(F, T)$ admits a $D(I)$-closure.
Proof. We have already proved that $D$-orderings admit closures, and thus we may assume that $|I|>1$. It has also already been shown in [Sch] that valuation fans admit closures. Here is a more general situation and a different proof, that consists again in transpositions of the proofs of Theorem 8.11 and Corollary 8.12. As in Theorem 8.11, if $t \in T$ and $L=F(\sqrt{t})$, applying Proposition 8.3, we find a valuation $v$ on $F$ such that $\bar{T}:=\pi_{v}\left(U_{v} \cap T\right)$ is either an ordering or a $D$-ordering. By Lemma 8.10, $T_{1}$ is a $D(J)$-ordering contained in $T$. Taking any valuation $w$ on $L=F(\sqrt{t})$ extending $v$, we extend $\bar{T}$ to $\tilde{T}$ in $L_{w}$. By Lemma 8.10 we obtain a $D(K)$-ordering $T_{2}$ in $L$. We enlarge it to a $D\left(K^{\prime}\right)$-ordering $T_{2}^{\prime}$, according to the three cases (1), (2), (3), replacing $T_{2} \cup-T_{2}$ by $T_{2}$. As in the case for $C(I)$-ordered fields, the only serious change is in proving that $\dot{L}=T_{2}^{\prime} \dot{F}$, and the proof is identical to that for $C(I)$-ordered fields.

## §9. Galois groups and additive structures (2)

Throughout this paper, we have considered a number of subgroups $H$ of $\mathcal{G}_{F}$ which behave pretty well, in that we have a certain control over the additive structure of the associated orderings, and we are able to make closures. Actually some of these groups $H$ have an additional property which helped us in a subtle but important way. Let us introduce the following definition and notation.

## Definition and Notation 9.1.

(1) We say that an essential subgroup $H$ of $\mathcal{G}_{F}$ is lifted if we can write $\mathcal{G}_{F}=$ $G \rtimes H$ for some normal subgroup $G$ of $\mathcal{G}_{F}$. This means that $H$ is not only a subgroup of $\mathcal{G}_{F}$, but also a quotient $\mathcal{G}_{F} \longrightarrow H$ such that $H \longrightarrow \mathcal{G}_{F} \longrightarrow H$ is the identity map. The $H$-ordering $P_{H}$ is called a lifted ordering. (The name lifted was chosen because such an $H$ corresponds, as a quotient of $\mathcal{G}_{F}$, to a Galois extension of $F$ inside $F^{(3)}$, of group $H$, which can be lifted as a Galois subextension of $F^{(3)}$ of same group $H$.)
(2) If we want to realize some subgroup $H$ of $\mathcal{G}_{F}$ as a $\mathcal{G}_{K}$ for some field $K$, we certainly need to use an $H$ which satisfies known properties of $W$-groups. In particular, if $H \neq\{1\}, C_{2}$, then by Corollary 2.18 of [MiSp2], we see that $H$ can be embedded in a suitable product $\prod_{I} D \times \prod_{J} C_{4}$, where each factor is a quotient of $H$. According to the use in universal algebra, see e.g. [Gr, p. 123], we refer to $H$ as the subdirect product of $\prod_{I} D \times \prod_{J} C_{4}$. (Also we say that $H$ as above satisfies the subdirect product condition.)
(3) We say that an essential subgroup $H$ of $\mathcal{G}_{F}$ is a fair subgroup if it is lifted and if it is either $\{1\}$ or $C_{2}$ or a subdirect product of some $\prod_{I} D \times \prod_{J} C_{4}$. The $H$-ordering $P_{H}$ will be called a fair ordering if $H$ is a fair subgroup of $\mathcal{G}_{F}$.
Remark 9.2. We observed in Example 6.4 that the subgroup $H=\langle\sigma, \tau\rangle \cong$ $C_{4} * C_{4}$ in $\mathcal{G}_{\mathbb{Q}_{2}}$ has associated $H$-ordering $T=\dot{F}^{2} \cup 5 \dot{F}^{2}, F=\mathbb{Q}_{2}$, such that $T+T$ is not multiplicatively closed. We now use the description of $\mathcal{G}_{F}=\mathbb{G}_{2}$
as in Example 2.9, to show that $H$ is not a lifted subgroup of $\mathcal{G}_{F}$. Suppose instead that $H$ is a lifted subgroup of $\mathcal{G}_{F}$. Then there exists a subgroup $G$ of $\mathcal{G}_{F}$ such that $\mathcal{G}_{F}=G \rtimes H$. Then $G$ must contain some element of the form $\alpha=\rho h \phi$ where $\rho$ is an element of $\mathcal{G}_{F}$ such that $\rho, \sigma, \tau$ generate $\mathcal{G}_{F}$ and $\sigma^{2}[\rho, \tau]=1, h \in H$ and $\phi$ is some element in $\Phi\left(\mathcal{G}_{F}\right)$. Because $G$ is a normal subgroup of $\mathcal{G}_{F}$ we see that $\alpha \in G$ implies $\alpha^{-1}\left(\tau^{-1} \alpha \tau\right)=[\alpha, \tau] \in G$ as well. Hence $[\alpha, \tau]=[\rho h \phi, \tau]=[\rho, \tau][h, \tau] \in G$. On the other hand $[\rho, \tau][h, \tau]=$ $\sigma^{2}[h, \tau] \in H$. Because $\mathcal{G}_{F}=G \rtimes H$ we see $G \cap H=\{1\}$ and thus $\sigma^{2}[h, \tau]=1$. This equality is impossible as $H$ is a free group in category $\mathcal{C}$. Therefore $H$ is not lifted.

Observe that it is sometimes fairly easy to establish the "fairness" of a given subgroup. For example if $H=\langle\sigma\rangle$ is an essential subgroup of $\mathcal{G}_{F}$ of order 2, then for $f \notin P_{H}$ the restriction $H \longrightarrow \operatorname{Gal}(F(\sqrt{f}) / F)$ induces an isomorphism. Since the subdirect product condition is empty, $H$ is fair. We can also readily check the following:

Proposition 9.3. Let $\varphi: D(I) \longrightarrow \mathcal{G}_{F}$ be an essential embedding. Then $\varphi(D(I))$ is a lifted subgroup of $\mathcal{G}_{F}$. As the subdirect product condition is also trivially satisfied, it is a fair subgroup of $\mathcal{G}_{F}$.
Proof. Consider a $D(I)$-ordering $T$ of $F$ for some $|I| \geq 1$. Pick a basis for $\dot{F} / T$ of the form $\{[-1]\} \cup\left\{\left[a_{i}\right], i \in I\right\}$. (As usual $[f]$ means the class represented by $f$ in the factor group $\dot{F} / T$.) Set $K / F=F\left(\sqrt{-1}, \sqrt[4]{a_{i}}: i \in I\right)$. Then $\operatorname{Gal}(K / F) \cong$ $\left(\prod_{I} C_{4}\right) \rtimes C_{2}$, where we can choose generators $\bar{\tau}_{i}, i \in I$ for factors in the inner product and $\bar{\sigma}$ for the outer factor such that $\bar{\sigma}(\sqrt{-1})=-\sqrt{-1}, \bar{\sigma}\left(\sqrt[4]{a_{i}}\right)=$ $\sqrt[4]{a_{i}}, \bar{\tau}_{i}(\sqrt{-1})=\sqrt{-1}$ and $\bar{\tau}_{i}\left(\sqrt[4]{a_{i}}\right)=\sqrt{-1} \sqrt[4]{a}, \bar{\tau}_{i}\left(\sqrt[4]{a}{ }_{j}\right)=\sqrt[4]{a_{j}}$ for $j \neq i$. Moreover the action of $\bar{\sigma}$ on $\prod_{I} C_{4}$ is described as $\bar{\sigma}^{-1} \bar{\tau}_{i} \bar{\sigma}=\bar{\tau}_{i}^{3}$ for each $i \in I$. (Or equivalently $\bar{\sigma}^{-1} \bar{\tau} \bar{\sigma}=\bar{\tau}^{-1}$ for each $\bar{\tau} \in \prod_{I} C_{4}$.)
Pick any elements $\sigma, \tau_{i}, i \in I \in H:=\varphi(D(I))$ such that their homomorphic image from $H$ to $\operatorname{Gal}(K / F)$ are elements $\bar{\sigma}, \bar{\tau}_{i}, i \in I$. This is possible as $H$ surjects on $\operatorname{Gal}(K / F)$. Then the essential subgroup $H$ of $\mathcal{G}_{F}$ is generated by the minimal set of generators $\left\{\sigma, \tau_{i}, i \in I\right\}$. Moreover the natural restriction map $r: H \longrightarrow \operatorname{Gal}(K / F)$ is an isomorphism, as $r$ takes the generators of $H$ to the generators of $\operatorname{Gal}(K / F)$ and both sets of generators satisfy the same relations.

Now we consider $C_{4}$-orderings and determine when they are fair orderings. Observe that a $C_{4}$-ordering is automatically fair provided it is lifted, so it is enough to decide when a $C_{4}$-ordering $T$ is lifted.

Proposition 9.4. Let $T$ be a $C_{4}$-ordering of $F$. Then $T$ is lifted if and only if there exists an element $f \in\left(F^{2}+F^{2}\right) \backslash(T \cup\{0\})$.
Proof. Suppose that $T$ is a $C_{4}$-ordering of $F, T=P_{H}$ for $H \cong C_{4}$, and $H$ is essentially embedded in $\mathcal{G}_{F}$. Suppose also that $f \in\left(F^{2}+F^{2}\right) \backslash(T \cup\{0\})$. Then since $f \notin T$ and $T \supset \dot{F}^{2}$, we see that $f \notin F^{2}$ and a $C_{4}^{f}$-extension $K$ of $F$ exists. Because $f \in \dot{F} \backslash T$, an element $h \in H$ exists such that $h(\sqrt{f})=-\sqrt{f}$.

Then the image of $h$ in $\operatorname{Gal}(K / F)$ under the natural homomorphism $H \longrightarrow$ $\operatorname{Gal}(K / F)$ is a generator of $\operatorname{Gal}(K / F)$. Therefore the homomorphism is in fact an isomorphism, and $H$ is lifted as asserted. Assume now that $H \cong C_{4}$ is a lifted subgroup of $\mathcal{G}_{F}$. Then a surjective homomorphism $\varphi: \mathcal{G}_{F} \longrightarrow C_{4}$ exists, which induces an isomorphism $\psi: H \longrightarrow C_{4}$. Let $K$ be the fixed field of the kernel of $\varphi$. Then $K / F$ is a Galois extension on $\operatorname{Gal}(K / F) \cong C_{4}$. Let $F(\sqrt{f})$ be a unique quadratic extension of $F$ contained in $K$. Also let $T=P_{H}$. Then $H$ acts nontrivially on $\sqrt{f}$ and $f \in\left(F^{2}+F^{2}\right) \backslash\{0\}$. Hence $f \in\left(F^{2}+F^{2}\right) \backslash(T \cup\{0\})$ as claimed.

Example 9.5. The following simple example shows that we cannot drop the condition $\exists f \in\left(F^{2}+F^{2}\right) \backslash(T \cup\{0\})$ from the proposition above, and that unfair $C_{4}$-orderings exist in nature. Consider again $F=\mathbb{Q}_{2}$ and set $T=$ $\left(F^{2}+F^{2}\right) \backslash\{0\}$. Then $T$ is a subgroup of $\dot{F}$ of index 2 . Because $\mathbb{Q}_{2}$ is not a formally real field, $\mathbb{Q}_{2}$ does not admit any usual ordering, and $T$ is a $C_{4^{-}}$ ordering of $F$. However $T$ contains all sums of two squares, and therefore $T$ is not lifted.
On the bright side, we wish to point out that for each $C_{4}$-ordering there exists a quadratic extension of the base field, and an extension of the original $C_{4}$ ordering on this quadratic extension where this extended ordering become a fair ordering. In other words an unfair ordering may become fair in some algebraic extension. More precisely we have the following proposition, in which we use Definition 1.4(4) of an $H$-extension

Proposition 9.6. Let $T$ be a $C_{4}$-ordering in $F$. If $T$ is not fair, there exists $t \in T$ and a $C_{4}$-extension $(F(\sqrt{t}), V)$ of $(F, T)$ such that $V$ is a fair ordering in $F(\sqrt{t})$.

Proof. Suppose that $T$ is a $C_{4}$-ordering in $F$. Then by Proposition 5.4 there must exist an element $t \in T$ such that $1+t \notin T$. If $T$ is not a fair ordering, we know from the characterization of fair orderings in Proposition 9.4 that $t \notin \dot{F}^{2}$. Hence $K=F(\sqrt{t})$ is a quadratic extension of $F$ and $[K: F]=2$. From the proof of Proposition 4.2, we know that there exists some subgroup $V$ in $K$ such that $|\dot{K} / V|=2$ and $V \cap \dot{F}=T$. Then $V$ is a $C_{4}$-ordering of $K$, and $V$ is fair as $1+(\sqrt{t})^{2} \notin V$.

In this section we merely give a few examples of fair orderings and are not pursuing a systematic check of which orderings considered in this paper are fair and which will become fair after extension to a suitable 2-extension of the base field. The development of a theory of fair orderings of fields is planned for a subsequent paper.
We complete our family of examples of orderings by considering $H=\mathcal{F}(I)$, where $I$ is some nonempty index set and $\mathcal{F}(I)$ is the free pro-2-group in the category $\mathcal{C}$, on a minimal set $\left\{\sigma_{i} \mid i \in I\right\}$ of generators $I$. (We assume as usual that each open subgroup $V$ of $\mathcal{F}(I)$ contains all but finitely many $\sigma_{i}, i \in I$. See [Koc, Chapter 4].)

Proposition 9.7. Let $K / F$ be a Galois extension such that $\operatorname{Gal}(K / F) \cong$ $\mathcal{F}(I)=\left\langle\sigma_{i} \mid i \in I\right\rangle$ where $\left\{\sigma_{i}, i \in I\right\}$ is a family of minimal generators of the free pro-2-group $\mathcal{F}(I)$ in our category $\mathcal{C}$. Then there exists a fair $\mathcal{F}(I)$-ordering in $F$.

Proof. We first embed the group $\mathcal{F}(I)$ essentially in $\mathcal{G}_{F}$. Since $F^{(3)}$ is the maximal Galois subextension of a quadratic closure $F_{q}$ of $F$ such that $\operatorname{Gal}\left(F^{(3)} / F\right)$ belongs to the category $\mathcal{C}$, and since $\mathcal{F}(I)$ also belongs to $\mathcal{C}$, we see that $K \subset F^{(3)}$. Therefore there exists a surjective natural homomorphism $\pi: \mathcal{G}_{F} \longrightarrow \operatorname{Gal}(K / F)$.
It is well known that there exists a continuous map $s: \operatorname{Gal}(K / F) \longrightarrow \mathcal{G}_{F}$ such that $\pi \circ s$ is the identity map on $\operatorname{Gal}(K / F)$ (See [Koc, 1.3]). (Here we use only the fact that both groups $\operatorname{Gal}(K / F)$ and $\mathcal{G}_{F}$ are profinite groups.) Set $s\left(\sigma_{i}\right)=\omega_{i}$ for each $i \in I$. Then for each open subgroup $V$ of $\mathcal{G}_{F}$ the set $s^{-1}(V)$ is an open subset of $\operatorname{Gal}(K / F)$, and because open subgroups of $\operatorname{Gal}(K / F)$ form a basis for the topology of $\operatorname{Gal}(K / F)$ we see that all but finitely many $\sigma_{i}, i \in I$, are in $\sigma^{-1}(V)$. Hence all but finitely many $\omega_{i}$ are in $V$.
Because $\mathcal{F}(I)$ is a free object of $\mathcal{C}$ on the set of generators $\left(\sigma_{i}\right), i \in I$ we see that there exists a continuous homomorphism $p: \operatorname{Gal}(K / F) \longrightarrow \mathcal{G}_{F}$ such that $p\left(\sigma_{i}\right)=\omega_{i}$ for each $i \in I$. Set $H=p(\operatorname{Gal}(K / F))$. Then we have $\pi \circ p=1$ and $\mathcal{G}_{F} \cong \operatorname{ker} \pi \rtimes H$. Moreover, $\pi$ restricted to $H$ induces an isomorphism $\varphi: H \longrightarrow \operatorname{Gal}(K / F)$. Observe that $\varphi\left(\omega_{i}\right)=\sigma_{i}$ for each $i \in I$. Because $\sigma_{i}$ $\bmod \phi(\operatorname{Gal}(K / F))$ are topologically independent, we see that $\omega_{i}$ must be topologically independent $\bmod \phi\left(\mathcal{G}_{F}\right)$. This means that $\left\{\omega_{i}, i \in I\right\}$ generates the essential subgroup $H$ of $\mathcal{G}_{F}$.
One can check that $\mathcal{F}(I)$ is a subdirect product of its dihedral and $C_{4}$ quotients directly from the structure of $\mathcal{F}(I)$, but it is also possible simply to observe that $\mathcal{F}(I)$ is the $W$-group of a suitable field $A$ and all $W$-groups have this property. That each $\mathcal{F}(I)$ is the $W$-group of a suitable field $A$ follows from the fact that for each index set $I \neq \phi$ we can find a field $A$ such that the Galois group of its quadratic closure is a free pro-2-group (see e.g., [GM, page 98]), and therefore its $W$-group is $\mathcal{F}(I)$.

The following corollary applies, for example, in the case of $F=\mathbb{Q}_{p}(t)$.
Corollary 9.8. Let $F$ be the quotient field of a complete local integral domain properly contained in $F$. Let $\mathcal{F}(I)$ be any free object of category $\mathcal{C}$ on generators $I$, where $I$ is a nonempty finite set. Then $F$ admits a fair $\mathcal{F}(I)$-ordering.

Proof. From Proposition 9.7 we see that it is sufficient to show that each group $\mathcal{F}(I), I$ finite and nonempty, occurs as a Galois group over $F$. Harbater's wellknown result [Har, p. 186] says that each finite group is realizable over $F$. (For a very nice and rather elementary proof of this result see [HaVöl, Theorem 4.4].)

Let us fix the following notation.

Notation 9.9. Let $i: F_{1} \longrightarrow F_{2}$ be a quadratic extension and let $i^{\star}: \mathcal{G}_{F_{2}} \longrightarrow$ $\mathcal{G}_{F_{1}}$ be the associated restriction map. (See e.g. [MiSm3] for the existence of this map.) Let $H_{2}$ be a subgroup of $\mathcal{G}_{F_{2}}$ and let $H_{1}=i^{\star}\left(H_{2}\right)$. Assume $H_{1}$ is essential in $\mathcal{G}_{F_{1}}$. Observe that this property is not automatically satisfied since the image of an essential group under the restriction map $i^{\star}$ need not be essential. (See Remark 7.8 for an example exhibiting such a case.) When this is the case, we say that the extension $\left(F_{1}, H_{1}\right) \longrightarrow\left(F_{2}, H_{2}\right)$ is essential. Put $T_{1}=P_{H_{1}}, T_{2}=P_{H_{2}}$. Then it follows that $T_{1}=T_{2} \cap F_{1}$.
If we are working with fair groups $H$ as above, then we can show that for an essential quadratic extension $\left(F_{1}, H_{1}\right) \longrightarrow\left(F_{2}, H_{2}\right)$, the additive structure of the associated orderings is preserved if and only if $i^{\star}$ induces an isomorphism between $H_{2}$ and $H_{1}$.

Theorem 9.10. Assume the hypotheses in Notation 9.9 hold and that $H_{1}, H_{2}$ are fair subgroups of $\mathcal{G}_{F_{1}}, \mathcal{G}_{F_{2}}$ respectively. Then the restriction $i^{\star}$ induces an isomorphism between $H_{2}$ and $H_{1}$ if and only if $\dot{F}_{1} / T_{1} \cong \dot{F}_{2} / T_{2}$ and for each $a \in F_{1}, T_{1}+a T_{1}=\left(T_{2}+a T_{2}\right) \cap F_{1}$.
Since the proof is a bit long and since the two directions are not using the same assumptions on $H_{1}, H_{2}$, we split the theorem in two parts, Proposition 9.11 and Proposition 9.12
Proposition 9.11. Assume that $H_{1}$ is lifted. Following Notation 9.9, if the restriction $i^{\star}$ induces an isomorphism between $H_{2}$ and $H_{1}$, then $\dot{F}_{1} / T_{1} \cong \dot{F}_{2} / T_{2}$ and for each $a \in F_{1}, \quad T_{1}+a T_{1}=\left(T_{2}+a T_{2}\right) \cap F_{1}$.
Proof. We know that $\dot{F}_{i} / T_{i}$ is the Pontrjagin dual of $H_{i} / \Phi\left(H_{i}\right)$ for $i=1,2$. Thus the natural isomorphism $H_{2} \longrightarrow H_{1}$ yields an isomorphism $\dot{F}_{1} / T_{1} \cong$ $\dot{F}_{2} / T_{2}$. In order to show that for each $a \in F_{1}$ we have $T_{1}+a T_{1}=\left(T_{2}+a T_{2}\right) \cap F_{1}$, it is enough to show that for every $b, c \in \dot{F}_{1} \backslash T_{1}$, if there exists $s_{2}, t_{2} \in T_{2}$ such that $b s_{2}+c t_{2}=1$, then there exists $s_{1}, t_{1} \in T_{1}$ such that $b s_{1}+c t_{1}=1$. Indeed, assume that the latter condition involving $b, c \in \dot{F}_{1} \backslash T_{1}$ is valid. Consider any $a \in \dot{F}_{1}$ and any relation $u_{2}+a v_{2}=d$, where $u_{2}, v_{2} \in T_{2} \cup\{0\}$ and $d \in \dot{F}_{1}$. We want to show that there exist elements $u_{1}, v_{1} \in T_{1} \cup\{0\}$ such that $u_{1}+a v_{1}=d$. If $u_{2}=0$ then $v_{2} \in \dot{F}_{1} \cap T_{2}=T_{1}$, and we are done. If $v_{2}=0$ then $u_{2}=d \in \dot{F}_{1} \cap T_{2}=T_{1}$, and again we are done. Then assume $u_{2}, v_{2} \in T_{2}$. If $-a \in T_{1}$, let us write $d=s^{2}-t^{2}$ for some elements $s, t \in \dot{F}_{1}$. We then have $d=s^{2}+a\left(-a t^{2} / a^{2}\right) \in T_{1}+a T_{1}$. Hence we may assume that $-a \notin T_{1}$. Finally we also assume that $d \notin T_{1}$. From the equation $u_{2}+a v_{2}=d$ we obtain $u_{2}=d-a v_{2}$, and since $u_{2}, v_{2} \in T_{2}$ we can rewrite this equation as $1=d s_{2}-a t_{2}$ where $d,-a \in \dot{F}_{1} \backslash T_{1}$. Using our hypothesis we see that there exist elements $s_{1}, t_{1} \in T_{1}$ such that $1=d s_{1}-a t_{1}$. Hence $d \in T_{1}+a T_{1}$ as required.
Now take $b, c \in \dot{F}_{1} \backslash T_{1}$ and assume that $b s_{2}+c t_{2}=1$ for some $s_{2}, t_{2} \in T_{2}$. Then the quaternion algebra $\left(\frac{b s_{2}, c t_{2}}{F_{2}}\right)$ splits. We consider the following cases.
(1) Suppose $b s_{2}, c t_{2}$ are linearly independent in $\dot{F}_{2} / T_{2}$. Then they are also independent modulo $\dot{F}_{2}^{2}$, and by Proposition 1.5 we have a dihedral extension
$L_{2} / F_{2}$ such that $F_{2}\left(\sqrt{b s_{2}}, \sqrt{c t_{2}}\right) \subset L_{2}$ and $\operatorname{Gal}\left(L_{2} / F_{2}\left(\sqrt{b c s_{2} t_{2}}\right)\right) \cong C_{4}$. In particular we have an exact sequence
$1 \longrightarrow C_{2} \longrightarrow \operatorname{Gal}\left(L_{2} / F_{2}\right) \cong D \longrightarrow \operatorname{Gal}\left(F_{2}\left(\sqrt{b s_{2}}, \sqrt{c t_{2}}\right) / F_{2}\right) \cong C_{2} \times C_{2} \longrightarrow 1$.
Let $\theta$ denote the restriction map from $H_{2}$ to $\operatorname{Gal}\left(F_{2}\left(\sqrt{b s_{2}}, \sqrt{c t_{2}}\right) / F_{2}\right)$. We show it is surjective. Denote by $u_{1}, u_{2}$ the two generators of $\operatorname{Gal}\left(F_{2}\left(\sqrt{b s_{2}}, \sqrt{c t_{2}}\right) / F_{2}\right)$ defined by $u_{1}\left(\sqrt{b s_{2}}\right) / \sqrt{b s_{2}}=-1, u_{1}\left(\sqrt{c t_{2}}\right) / \sqrt{c t_{2}}=1, u_{2}\left(\sqrt{b s_{2}}\right) / \sqrt{b s_{2}}=$ $1, u_{2}\left(\sqrt{c t_{2}}\right) / \sqrt{c t_{2}}=-1$. We may look at $u_{1}, u_{2}$ as linear functions on the $\mathbb{F}_{2}$-vector subspace of $\dot{F}_{2} / \dot{F}_{2}^{2}$ spanned by $b s_{2}, c t_{2}$, which are assumed to be independent, and since $b T_{2} \cap c T_{2}=\emptyset$, we may extend them to linear functions $v_{1}, v_{2}$ defined on the subspace generated by $b T_{2}, c T_{2}$, by putting $v_{i}(x)=u_{i}(b)$ if $x \in b T_{2}$ and $v_{i}(x)=u_{i}(c)$ if $x \in c T_{2}$. Then $v_{i}$ may be viewed as a function on the $\mathbb{F}_{2}$-vector subspace generated by the cosets $b T_{2}, c T_{2}$ in $\dot{F}_{2} / T_{2}$. Again, these functions $v_{i}$ 's may be extended to $w_{i}$ defined on the whole vector space $\dot{F}_{2} / T_{2}$. By duality, one has $\left(\dot{F}_{2} / T_{2}\right)^{\star} \cong H_{2} / \Phi\left(H_{2}\right)$, and the $w_{i}$ 's yield to elements in $H_{2} / \Phi\left(H_{2}\right)$ which may be lifted as elements $h_{1}, h_{2} \in H_{2}$. Since the duality is precisely given by the pairing $H_{2} / \Phi\left(H_{2}\right) \times \dot{F}_{2} / T_{2} \longrightarrow\{ \pm 1\}$ defined by $(h, f) \mapsto h(\sqrt{f}) / \sqrt{f}$, it is immediate that $h_{i}$ goes to $u_{i}$ under the restriction map $\theta: H_{2} \longrightarrow \operatorname{Gal}\left(F_{2}\left(\sqrt{b s_{2}}, \sqrt{c t_{2}}\right) / F_{2}\right)$. This shows the surjectivity of $\theta$. Since $\theta$ factors through $\psi: H_{2} \longrightarrow \operatorname{Gal}\left(L_{2} / F_{2}\right) \cong D$ and since the kernel of $\operatorname{Gal}\left(L_{2} / F_{2}\right) \longrightarrow \operatorname{Gal}\left(F_{2}\left(\sqrt{b s_{2}}, \sqrt{c t_{2}}\right) / F_{2}\right)$ is the Frattini subgroup of $\operatorname{Gal}\left(L_{2} / F_{2}\right)$, we see that $\psi$ is also surjective. This means that $D$ may be viewed as a quotient of $H_{2}$ and that we have inclusion maps $F_{2}^{(3)}{ }^{H_{2}} \longrightarrow L_{2}^{\prime} \longrightarrow F_{2}^{(3)}$ such that $\operatorname{Gal}\left(L_{2}^{\prime} / F_{2}^{(3)}{ }^{H_{2}}\right) \cong D$. Since $i^{\star}\left(H_{2}\right)=H_{1}$, applying $i^{\star}$ to this diagram gives us another diagram $F_{1}^{(3)^{H_{1}}} \longrightarrow L_{1}^{\prime} \longrightarrow F_{1}^{(3)}$ with $\operatorname{Gal}\left(L_{1}^{\prime} / F_{1}^{(3)}{ }^{H_{1}}\right) \cong D$. Since $H_{1}$ is lifted, we know that there exists an $H_{1}$-extension $K / F_{1}$ inside $F_{1}^{(3)}$ containing a $D$-extension $L_{1} / F_{1}$. This extension is a $D^{u, v}$-extension for suitable $u, v \in F_{1}$ by Proposition 1.5. We claim that we have $u=b s_{1}, v=c t_{1}$ for suitable $s_{1}, t_{1} \in T_{1}$. Consider the surjective homomorphism

$$
\theta: H_{2} \longrightarrow \operatorname{Gal}\left(F_{2}\left(\sqrt{b s_{2}}, \sqrt{c t_{2}}\right) / F_{2}\right)
$$

defined above. Then $\theta$ factors through the surjective homomorphism $\psi: H_{2} \longrightarrow$ $\operatorname{Gal}\left(L_{2} / F_{2}\right) \cong D$. Using the isomorphism $\beta: H_{2} \longrightarrow H_{1}$ induced by $i^{\star}$ and our construction of $L_{1} / F_{1}$, we see that the homomorphism $\psi: H_{2} \longrightarrow$ $\operatorname{Gal}\left(L_{2} / F_{2}\right)$ is compatible, via identification of $H_{2}$ with $H_{1}$ using $i^{\star}$, with the restriction homomorphism $\tilde{\psi}: H_{1} \longrightarrow \operatorname{Gal}\left(L_{1} / F_{1}\right)$. Passing to the quotients $\operatorname{Gal}\left(F_{2}\left(\sqrt{b s_{2}}, \sqrt{c t_{2}}\right) / F_{2}\right)$ and $\operatorname{Gal}\left(F_{1}(\sqrt{u}, \sqrt{v}) / F_{1}\right)$ of $\operatorname{Gal}\left(L_{2} / F_{2}\right)$ and $\operatorname{Gal}\left(L_{1} / F_{1}\right)$ respectively, we see that we can identify the homomorphism $\theta: H_{2} \longrightarrow \operatorname{Gal}\left(F_{2}\left(\sqrt{b s_{2}}, \sqrt{c t_{2}}\right) / F_{2}\right)$ with the restriction homomorphism $\tilde{\theta}: H_{1} \longrightarrow \operatorname{Gal}\left(F_{1}(\sqrt{u}, \sqrt{v}) / F_{1}\right)$ via the isomorphism $i^{\star}: H_{2} \longrightarrow H_{1}$. Finally from the natural isomorphism $\dot{F}_{1} / T_{1} \cong \dot{F}_{2} / T_{2}$ we may assume that $u=b s_{1}$ and $v=c t_{1}$ for suitable elements $s_{1}, t_{1} \in T_{1}$. By Proposition 1.5, this implies
that the quaternion algebra $\left(\frac{b s_{1}, c t_{1}}{F_{1}}\right)$ splits, and that there exist $\tilde{s_{1}}, \tilde{t_{1}} \in T_{1}$ such that $b \tilde{s_{1}}+c \tilde{t_{1}}=1$.
Suppose now that $b s_{2}, c t_{2}$ are linearly dependent in $\dot{F}_{2} / T_{2}$. Then $b$ and $c$ are equal modulo $T_{2}$ and we may assume $b=c$. There are still two more cases to consider.
(2) Suppose we have $c s_{2}+c t_{2}=1$ with $s_{2}=t_{2} \bmod \dot{F}_{2}^{2}$. By Proposition 1.5, there exists a $C_{4}^{c s_{2}}$-extension $L_{2} / F_{2}$ with $F_{2}\left(\sqrt{c s_{2}}\right) \subset L_{2}$. Using arguments similar to those in (1), we show that the restriction $\psi: H_{2} \longrightarrow \operatorname{Gal}\left(L_{2} / F_{2}\right)$ is onto, and we find $s_{1} \in T_{1}$ such that $\left(\frac{c s_{1}, c s_{1}}{F_{1}}\right)$ splits. This implies that there exist $\tilde{s_{1}}, \tilde{t_{1}} \in T_{1}$ such that $c \tilde{s_{1}}+c \tilde{t_{1}}=1$.
(3) Suppose we have $c s_{2}+c t_{2}=1$ with $s_{2} \neq t_{2} \bmod \dot{F}_{2}^{2}$. As in (1) we find $L_{2}$ with $\operatorname{Gal}\left(L_{2} / F_{2}\right) \cong D$ and we have a tower of fields $F_{2} \longrightarrow$ $F_{2}\left(\sqrt{s_{2} t_{2}}\right) \longrightarrow F_{2}\left(\sqrt{c s_{2}}, \sqrt{c t_{2}}\right) \longrightarrow L_{2}$. Since $H_{2}$ fixes $F_{2}\left(\sqrt{s_{2} t_{2}}\right)$, the restriction map $\psi: H_{2} \longrightarrow \operatorname{Gal}\left(L_{2} / F_{2}\right)$ induces a surjective homomorphism $\psi^{\prime}: H_{2} \longrightarrow \operatorname{Gal}\left(L_{2} / F_{2}\left(\sqrt{s_{2} t_{2}}\right)\right) \cong C_{4}$. We finish with arguments as in (2) and replacing $F_{2}$ by $F_{2}\left(\sqrt{s_{2} t_{2}}\right)$, we find $\tilde{s_{1}}, \tilde{t_{1}} \in T_{1}$ such that $c \tilde{s_{1}}+c \tilde{t_{1}}=1$.

We now prove the result in the other direction.
Proposition 9.12. Let $H_{1}, H_{2}$ be as in Notation 9.9 and assume they are fair subgroups. If the inclusion $i: F_{1} \longrightarrow F_{2}$ induces an isomorphism $\dot{F}_{1} / T_{1} \longrightarrow$ $\dot{F}_{2} / T_{2}$ and if $\left(T_{2}+a T_{2}\right) \cap \dot{F}=T_{1}+a T_{1}$ for any $a \in F_{1}$, then $i^{\star}$ induces an isomorphism between $H_{2}$ and $H_{1}$.

Proof. If $H_{2}=\{1\}$ then $H_{1}=\{1\}$ as well. If $H_{2}=C_{2}$ then $i^{\star}\left(H_{2}\right) \neq\{1\}$ because $T_{2}$ is a usual ordering in $\dot{F}_{2}$, and it cannot contain $\dot{F}_{1}$. However if $H_{1}$ were $\{1\}$ then $T_{1}=\dot{F}_{1}$. Therefore $i^{\star}$ induces an isomorphism between $H_{2}$ and $H_{1}$.
For the rest of our proof we assume that $H_{2} \neq\{1\}, C_{2}$. Call $\beta: H_{2} \longrightarrow H_{1}$ the restriction of $i^{\star}$ to $H_{2}$. Because $i^{\star}$ is a group homomorphism from $\mathcal{G}_{F_{2}}$ into $\mathcal{G}_{F_{1}}$, we have $i^{\star}\left(\Phi\left(\mathcal{G}_{F_{2}}\right)\right) \subset \Phi\left(\mathcal{G}_{F_{1}}\right)$. Also we have $\beta\left(\Phi\left(H_{2}\right)\right) \subset \Phi\left(H_{1}\right)$. Then the map $\beta$ induces $\hat{\beta}: H_{2} / \Phi\left(H_{2}\right) \longrightarrow H_{1} / \Phi\left(H_{1}\right)$, which is an isomorphism because its dual map $\dot{F}_{1} / T_{1} \longrightarrow \dot{F}_{2} / T_{2}$ is an isomorphism. By definition $\beta$ is onto. We want to show that $\beta$ is injective. From the fact that $\hat{\beta}$ is an isomorphism, we see that $\operatorname{ker} \beta \subseteq \Phi\left(H_{2}\right)$. Take a fixed set of minimal (topological) generators $\left(\sigma_{i}\right)_{i \in I}$ for $H_{2}$. Then $\gamma \in \Phi\left(H_{2}\right)$ has a unique description, up to a permutation, as $\gamma=\prod_{i \in I} \sigma_{i}^{2} \times \prod_{(u, v) \in K}\left[\sigma_{u}, \sigma_{v}\right]$ for some possibly infinite sets $I, K$.
To complete the proof we use the following lemma.
Lemma 9.13. Assume that $H_{1}, H_{2}, T_{1}, T_{2}$ are as in Proposition 9.12, and let $\delta$ be $\sigma_{i}^{2}$ or $\left[\sigma_{u}, \sigma_{v}\right]$. Suppose that we have a surjective map $\varphi: H_{2} \longrightarrow G$ where $G=D$ or $C_{4}$. Then there exists a group $\tilde{G}$ which is again either $D$ or $C_{4}$ and a homomorphism $\psi: H_{1} \longrightarrow \tilde{G}$ such that $\psi(\beta(\delta)) \neq 1 \in \tilde{G}$ if and only if $\varphi(\delta) \neq 1 \in G$. Moreover $\tilde{G}$ and the homomorphism $\psi$ depend only on $G$ and on the fields $F_{1}$ and $F_{2}$, but not on $\delta$.

Proof. (1) Assume first that $G=C_{4}$. Since $H_{2}$ is lifted, there exist an $H_{2^{-}}$ extension $K_{2} / F_{2}$ and a $C_{4}^{u}$-extension $L_{2}$ of $F_{2}$ with $F_{2} \longrightarrow F_{2}(\sqrt{u}) \longrightarrow L_{2} \longrightarrow$ $K_{2}$. Since $\dot{F}_{1} / T_{1} \cong \dot{F}_{2} / T_{2}$, there exist $a \in \dot{F}_{1}, s_{2} \in T_{2}$ such that $u=a s_{2}$. Let $\delta=\sigma^{2}$, which is the only case to be considered when $G=C_{4}$. Then $\varphi\left(\sigma^{2}\right) \neq 1 \in \operatorname{Gal}\left(L_{2} / F_{2}\right)$ if and only if $\varphi(\sigma)$ has order 4. Thus $\varphi\left(\sigma^{2}\right) \neq 1$ if and only if $\varphi(\sigma)$ generates $\operatorname{Gal}\left(L_{2} / F_{2}\right)$. This happens precisely when $\varphi(\sigma)\left(\sqrt{a s_{2}}\right)=$ $-\sqrt{a s_{2}}$. Since $H_{2}$, and thus $\varphi(\sigma)$, fixes $\sqrt{s_{2}}$, this is equivalent to $\varphi(\sigma)(\sqrt{a})=$ $-\sqrt{a}$. On the other hand, we know by Proposition 1.5 that the quaternion algebra $\left(\frac{a s_{2}, a s_{2}}{F_{2}}\right)$ splits, and this implies the existence of $s_{2}^{\prime}, t_{2}^{\prime} \in T_{2}$ such that $a s_{2}^{\prime}+a t_{2}^{\prime}=1$. From the assumption on the additive structure, this implies the existence of $s_{1}, t_{1} \in T_{1}$ such that $a s_{1}+a t_{1}=1$. Two cases are to be considered. (1.1) If $s_{1}=t_{1} \bmod \dot{F}_{1}^{2}$, then there is a $C_{4}^{a s_{1}}$-extension $L_{1}$ of $F_{1}$ with $F_{1} \longrightarrow F_{1}\left(\sqrt{a s_{1}}\right) \longrightarrow L_{1}$. Denoting by $\psi: H_{1} \longrightarrow \operatorname{Gal}\left(L_{1} / F_{1}\right)$ the restriction, because $H_{1}$ fixes $\sqrt{T_{1}}$ we have $\psi(\beta(\sigma))\left(\sqrt{a s_{1}}\right) / \sqrt{a s_{1}}=\psi(\beta(\sigma))(\sqrt{a}) / \sqrt{a}=$ $\varphi(\sigma)(\sqrt{a}) / \sqrt{a}=-1$, showing $\psi(\beta(\delta)) \neq 1 \in C_{4}=\tilde{G}$.
(1.2) If $s_{1} \neq t_{1} \bmod \dot{F}_{1}^{2}$, there is a $D^{a s_{1}, a t_{1}}$-extension $L_{1}$ of $F_{1}$ with $F_{1} \longrightarrow$ $F_{1}\left(\sqrt{s_{1} t_{1}}\right) \longrightarrow L_{1}$. Here $L_{1} / F_{1}\left(\sqrt{s_{1} t_{1}}\right)$ is a $C_{4}$-extension. Since $\beta(\sigma) \in H_{1}$ fixes $F_{1}\left(\sqrt{s_{1} t_{1}}\right), \psi(\beta(\sigma))$ is in the Galois group of the latter extension, which is again a $C_{4}$-extension. We then use the same argument as in (1.1) to conclude that $\psi(\beta(\delta)) \neq 1 \in \tilde{G}=C_{4}$.
(2) Assume $G=D$. Again there is an $H_{2}$-extension $K_{2}$ of $F_{2}$ and a $D^{a s_{2}, b s_{2}}$ extension $L_{2}$ of $F_{2}$ with $F_{2} \longrightarrow F_{2}\left(\sqrt{a b s_{2} t_{2}}\right) \longrightarrow L_{2} \longrightarrow K_{2}$. Since $\varphi$ is surjective, there is an element $\tau \in H_{2}$ such that $\tau\left(\sqrt{a b s_{2} t_{2}}\right) / \sqrt{a b s_{2} t_{2}}=-1$, or else $\varphi\left(H_{2}\right)$ would fix $F_{2}\left(\sqrt{a b s_{2} t_{2}}\right)$ and would be contained in a proper subgroup of $\operatorname{Gal}\left(L_{2} / F_{2}\right) \cong D$. This implies $a b \notin T_{2}$. Since there exist $s_{2}^{\prime}, t_{2}^{\prime} \in T_{2}$ such that $a s_{2}^{\prime}+b t_{2}^{\prime}=1$, we also have, by the assumption on the additive structures, $a s_{1}+b t_{1}=1$ for some $s_{1}, t_{1} \in T_{1}$. Since $a b \notin T_{1}$, we see that $a s_{1}, b t_{1}$ are independent modulo $\dot{F}_{1}^{2}$, and there is a $D^{a s_{1}, b t_{1}}$-extension $L_{1}$ of $F_{1}$ with $F_{1} \longrightarrow F_{1}\left(\sqrt{a b s_{1} t_{1}}\right) \longrightarrow L_{1}$. Denote by $\psi: H_{1} \longrightarrow \operatorname{Gal}\left(L_{1} / F_{1}\right) \cong D$ the restriction map.
(2.1) Suppose $\delta=\sigma^{2}$ and $\varphi(\delta) \neq 1$. Then $\varphi(\sigma)$ has order 4 and must fix the quadratic extension $F_{2}\left(\sqrt{a b s_{2} t_{2}}\right)$. Then it belongs to $\operatorname{Gal}\left(L_{2} / F_{2}\left(\sqrt{a b s_{2} t_{2}}\right)\right) \cong$ $C_{4}$. With the same arguments as in (1), we show that $\psi(\beta(\delta)) \neq 1$.
(2.2) Suppose $\delta=\left[\sigma_{u}, \sigma_{v}\right]$ and $\varphi(\delta) \neq 1$. Then none of $\varphi\left(\sigma_{u}\right), \varphi\left(\sigma_{v}\right)$ is in $\Phi(D)$ (i.e. they do not fix the biquadratic extension $\left.F_{2}\left(\sqrt{a s_{2}}, \sqrt{b t_{2}}\right)\right)$, and they act differently on this biquadratic extension. Since $\varphi\left(\sigma_{u}\right)$ (respectively $\varphi\left(\sigma_{v}\right)$ ) acts the same way on elements in $\sqrt{\dot{F}}$ as $\psi\left(\beta\left(\sigma_{u}\right)\right)$ (respectively $\psi\left(\beta\left(\sigma_{v}\right)\right)$, we see that $\psi(\beta(\delta)) \neq 1 \in G$.
To conclude the proof, we point out that in all cases above, we first associated $\tilde{G}$ with the given homomorphism $\varphi: H_{2} \longrightarrow G$ and only then checked that $\varphi(\delta) \neq 1 \in G$ is equivalent to $\psi(\beta(\delta)) \neq 1 \in \tilde{G}$.

We can now finish the proof of Proposition 9.12. Suppose $\gamma \neq 1 \in \Phi\left(H_{2}\right)$. Since $H_{2}$ satisfies the subdirect product condition, there exists a surjective
map $\varphi: H_{2} \longrightarrow G$ with $G \cong D$ or $C_{4}$ and with $\varphi(\gamma) \neq 1 \in G$. Recall that the minimal set of generators $\left(\sigma_{i}\right)_{i \in I}$ may be chosen in such a way that for any open set $U$ of $H_{2}$ there are at most finitely many $\sigma_{i}$ 's outside $U$. (See for example [Koc, Chapter 4].) Since $\operatorname{ker} \varphi$ is open, we may thus assume, when working with a given $\varphi$, that $\gamma=\gamma_{0} \times \gamma_{1}$, with $\gamma_{0}=\prod_{i \in I_{0}} \sigma_{i}^{2} \times \prod_{(u, v) \in K_{0}}\left[\sigma_{u}, \sigma_{v}\right]$, $\gamma_{1}=\prod_{i \in I_{1}} \sigma_{i}^{2} \times \prod_{(u, v) \in K_{1}}\left[\sigma_{u}, \sigma_{v}\right]$, with the following properties. The sets $I_{0}, K_{0}$ are finite. Any individual factor $\sigma_{i}^{2},\left[\sigma_{u}, \sigma_{v}\right]$ of $\gamma_{0}$ is not in $\operatorname{ker} \varphi$, while any individual factor of $\gamma_{1}$ is in $\operatorname{ker} \varphi$. We may assume that $\gamma=\gamma_{0}$, and in particular we have only a finite number $n$ of terms $\delta_{i}$ 's with $\delta_{i}=\sigma_{i}^{2}$ or $\left[\sigma_{u}, \sigma_{v}\right]$. The Frattini group $\Phi(G) \cong C_{2}$ may be written $\{1, \epsilon\}$, and each $\varphi\left(\delta_{i}\right)$ must be $\epsilon$, since it is not 1 by assumption. Since $\varphi(\gamma)=\epsilon^{n} \neq 1, n$ must be odd. By Lemma 9.13, we know that there exists a group $\tilde{G}$ which is again $D$ or $C_{4}$ and a homomorphism $\psi: H_{1} \longrightarrow \tilde{G}$, such that $\varphi\left(\delta_{i}\right)=\epsilon \neq 1$ is equivalent to $\psi\left(\beta\left(\delta_{i}\right)\right)=\epsilon \neq 1$. Because $n$ is odd, this shows that $\psi(\beta(\gamma)) \neq 1$, and therefore $\beta(\gamma) \neq 1$. This shows the injectivity of $\beta$ and finishes the proof of Proposition 9.12.

## §10. Concluding Remarks

In this article we have considered all $C(I)$ - and $S(I)$-orderings. These groups correspond to W -groups for $p$-adic fields, for odd primes $p$. In particular, the W-group $\mathcal{G}_{p}$ of $\mathbb{Q}_{p}$ is $C_{4} \times C_{4}$ for $p \equiv 1(4)$ and is $C_{4} \rtimes C_{4}$ for $p \equiv 3(4)$. It is then natural to look for a characterization of $\mathcal{G}_{2}$-orderings, i.e. those orderings corresponding to subgroups isomorphic to the W-group of $\mathbb{Q}_{2}$. This is currently under investigation [MiSm4].
For the field $\mathbb{Q}$, there is a unique $C_{2}$-ordering, which is the unique ordering on $\mathbb{Q}$. In addition there is a one-to-one correspondence between $C_{4} \times C_{4}$-orderings on $\mathbb{Q}$ and primes $p \equiv 1(4)$, and a one-to-one correspondence between $C_{4} \rtimes C_{4}$ orderings on $\mathbb{Q}$ and primes $p \equiv 3(4)$. In each case the correspondence is given by $T_{p}=\dot{\mathbb{Q}}_{p}^{2} \cap \mathbb{Q}$. It is not hard to see that each such intersection gives rise to an $H$-ordering of the appropriate type. To see that every such ordering may be obtained in this way, one shows that each such ordering corresponds to a certain valuation on $\mathbb{Q}$, and the valuations on $\mathbb{Q}$ are well-known to be classified by the primes. (See e.g. [End, Theorem 1.16].)
This observation then lends itself to an alternative perspective on the HasseMinkowski Theorem, which states that a quadratic form defined over $\mathbb{Q}$ is isotropic over $\mathbb{Q}$ if and only if it is isotropic over each $\mathbb{Q}_{p}$, including $\mathbb{Q}_{\infty}$, the real numbers. Using Hilbert's reciprocity law, one can prove that a ternary quadratic form is isotropic over $\mathbb{Q}$ if and only if it is isotropic over all but one of these fields. Thus we see that a ternary quadratic form over $\mathbb{Q}$ is isotropic if and only if it is isotropic with respect to all $C_{2^{-}},\left(C_{4} \times C_{4}\right)$-, and $\left(C_{4} \rtimes C_{4}\right)$ orderings on $\mathbb{Q}$.
We point out that the case of a ternary quadratic form over $\mathbb{Q}$, together with the clever use of Dirichlet's theorem on the existence of an infinite number of primes in an arithmetic progression, where first term and increment are
relatively prime, are the main ingredients of a proof of the full Hasse-Minkowski theorem over $\mathbb{Q}$. For a very nice exposition of the Hasse-Minkowski theorem over $\mathbb{Q}$, see [BS]. See also [L1, Chapter 6, Exercise 22].
It is easy however, to find a quaternary quadratic form $\varphi$ over $\mathbb{Q}$ such that $\varphi$ is isotropic over all $\mathbb{Q}_{p}, p$ is an odd prime, and $\mathbb{Q}_{\infty}=\mathbb{R}$ but $\varphi$ is anisotropic over $\mathbb{Q}_{2}$. For example $\varphi=X_{1}^{2}+X_{2}^{2}-7 X_{3}^{2}-31 X_{4}^{2}$ and $\psi=X_{1}^{2}+X_{2}^{2}+X_{3}^{2}-7 X_{4}^{2}$ are such forms.
In a subsequent paper we will present several applications of this theory to different kinds of local-global principles for quadratic forms. In order to get a sense of what can be done in this direction, we show below an example of a simple situation in which our theory applies.
Consider a field $F$. Recall that a $C(\emptyset)$-ordering $T$ on $F$ is an index 2 multiplicative subgroup of $\dot{F} / \dot{F}^{2}$ containing -1 . Additively speaking, it is a hyperplane containing -1 in the $\mathbb{F}_{2}$-vector space $\dot{F} / \dot{F}^{2}$. If $f \in \dot{F} \backslash\left(\dot{F}^{2} \cup-\dot{F}^{2}\right)$ and if $V$ is any subspace of $\dot{F} / \dot{F}^{2}$ such that $\dot{F} / \dot{F}^{2}=\operatorname{Span}\{f,-1\} \oplus V$, then $T:=\operatorname{Span}\{-1\}+V$ is a $C(\emptyset)$-ordering not containing $f$. Then the next lemma follows immediately.

Lemma 10.1. Let $C_{0}(F)$ denote the set of $C(\emptyset)$-orderings of $F$. Then $C_{0}(F)=$ $\emptyset$ if and only if $\dot{F}=\dot{F}^{2} \cup-\dot{F}^{2}$, and in general,

$$
\bigcap_{T \in C_{0}(F)} T=\dot{F}^{2} \cup-\dot{F}^{2}
$$

To every $C(\emptyset)$-ordering $T$ we associate a fixed closure $F_{T}$ of $F$ in the quadratic closure of $F$. Denote by $\left\langle\left\langle a_{1}, \ldots, a_{n}\right\rangle\right\rangle$ the Pfister form $\left\langle 1,-a_{1}\right\rangle \otimes \ldots \otimes\left\langle 1,-a_{n}\right\rangle$. (For the basic theory of Pfister forms see e.g. [L1, Chapter 10] or [Sc, Chapter 4]. Observe that both Lam and Scharlau denote by $\left\langle\left\langle a_{1}, \ldots, a_{n}\right\rangle\right\rangle$ the Pfister form $\left\langle 1, a_{1}\right\rangle \otimes \ldots \otimes\left\langle 1, a_{n}\right\rangle$.) Then we have the following.

Proposition 10.2. Assume $C_{0}(F) \neq \emptyset$ and let $\varphi: W(F) \longrightarrow$ $\prod_{T \in C_{0}(F)} W\left(F_{T}\right)$ denote the map induced by the inclusions $F \longrightarrow F_{T}$. Then $\operatorname{Ker} \varphi=I^{2} F+2 W(F)$ where IF denotes the fundamental ideal of $W(F)$.
Proof. For $T \in C_{0}(F)$ we have $\dot{F} / T=\{\overline{1}, \bar{f}\}$ for a certain $f \in \dot{F}$, and it is easy to see that $W\left(F_{T}\right) \cong C_{2}[\epsilon] / \epsilon^{2}$ and that the isomorphism, which we call $\pi$, is defined by $\pi(\langle\overline{1}\rangle)=1, \pi(\langle\bar{f}\rangle)=1+\epsilon$. If $a, b \in \dot{F}$ then the possibilities for $\bar{a}, \bar{b}$ are (1) $\bar{a}=1$ or $\bar{b}=1$, or (2) $\bar{a}=\bar{b}=\bar{f}$. In any case the image in $W\left(F_{T}\right)$ of the 2-fold Pfister form $\langle\langle a, b\rangle\rangle$ is in $2 W\left(F_{T}\right)=0$, and we have shown the inclusion $I^{2} F+2 W(F) \subseteq \operatorname{Ker} \varphi$.
Take $q \in \operatorname{Ker} \varphi$. Then $q \in I F$, because any odd-dimensional form is nonzero in $W\left(F_{T}\right)$. But it is known ([Pf, p. 122, Kor. to Satz 13]) that any element $q$ of $I F$ may be written $q=\langle\langle u\rangle\rangle+q_{1}$, with $q_{1} \in I^{2} F$. Since $q \in \operatorname{Ker} \varphi$, and $I^{2} F \subset \operatorname{Ker} \varphi$, we deduce $\langle\langle u\rangle\rangle \in \operatorname{Ker} \varphi$. The latter is equivalent to $u \in T$ for every $T$, meaning $u \in \dot{F}^{2} \cup-\dot{F}^{2}$, or in other words $\langle\langle u\rangle\rangle=0$ or 2 in $W(F)$.

Recall that a field $F$ is said to have virtual cohomological dimension $n$, denoted $\operatorname{vcd}(F)=n$, if $\left.H^{d}(\operatorname{Gal}(F(2)) / F(\sqrt{-1})), \mu_{2}\right)=0$ for $d>n$, and $\left.H^{n}(\operatorname{Gal}(F(2)) / F(\sqrt{-1})), \mu_{2}\right) \neq 0$. (If we also considered the case of $\mathbb{F}_{p}, p$ an odd prime, as coefficients of the cohomology groups of absolute Galois groups, it would be more appropriate to say that $F$ as above has a virtual 2-cohomological dimension equal to $n$.) If $\operatorname{vcd}(F) \leq 1$, then $I^{2} F$ is torsion-free. To see this, observe first that $\operatorname{vcd}(F) \leq 1$ implies each binary quadratic form over $F(\sqrt{-1})$ is universal. Then use [L1, Chapter 11, Theorem 1.8 and Exercise 20] to conclude that $I^{2} F$ is torsion free. An example of a formally real field $F$ with $v c d(F)=1$ is $F=\mathbb{R}(X)$. We have the following local-global principle:

Theorem 10.3. Let $F$ be a field with $\operatorname{vcd}(F) \leq 1$. Let $D_{0}(F)$ (resp. $C_{0}(F)$, $S_{0}(F)$ ) denote the set of usual orderings $X(F)$ (resp. $C(\emptyset)$-orderings, $S(\emptyset)$ orderings) of $F$. Then

$$
\Lambda: W(F) \longrightarrow \prod_{T \in D_{0}(F) \cup C_{0}(F) \cup S_{0}(F)} W\left(F_{T}\right)
$$

is injective. If $F$ is formally real, we may drop $S_{0}(F)$. (If not, we may drop $D_{0}(F)$.)
Proof. It is clear that a form $q \in \operatorname{Ker} \Lambda$ is in $I F$, and thus can be written $q=\langle\langle a\rangle\rangle+q_{2}$ with $q_{2} \in I^{2} F$. By Pfister's Local-Global Principle [L1, Chapter $8, \S 4], q$ is torsion and it is therefore the case for $\langle\langle a\rangle\rangle$ and $q_{2}$. (It is trivial when $D_{0}(F)=\emptyset$, and if not, we use the fact that the signature $\hat{q}$ of $q$ is 0 and that $\hat{q_{2}} \equiv 0(\bmod 4)$.)
Since $I^{2} F$ is torsion-free, one has $q_{2}=0$, and $q=\langle\langle a\rangle\rangle$. Since $q$ vanishes on $C_{0}(F)$, by Proposition 10.2 we have $a \in \dot{F}^{2} \cup-\dot{F}^{2}$. (If $C_{0}(F)=\emptyset$, this condition is trivially satisfied.) If the level $s(F)$ is 1 , our proof is completed. Otherwise $D_{0}(F) \cup S_{0}(F) \neq \emptyset$, which shows that $q \neq\langle\langle-1\rangle\rangle$. Thus $q=\langle\langle 1\rangle\rangle=0$.

Remark 10.4. In this case we even have a strong Hasse principle, that is a local-global principle for detecting whether a quadratic form is anisotropic rather than just hyperbolic. Indeed, the fact that each ternary form over $F(\sqrt{-1})$ is isotropic and [ELP, Theorem F] give us the strong Hasse principle for forms of rank greater than or equal to 3 . Then the use of $C_{0}(F), S_{0}(F)$ and $D_{0}(F)$ provides the result for rank 2 forms.
Finally let us point out that our results are closely related to some ideas in birational anabelian Grothendieck geometry. In particular there is a close connection between ideas explored in this paper and the work of Bogomolov, Tschinkel and Pop ([Bo], [BoT], [Po1], and [Po2]; see also Koenigsmann's thesis [K1] and paper [K2]). Roughly speaking, they establish that for certain fields $K$ the isomorphy type of $K$, modulo purely inseparable extensions of $K$, is functorially encoded in the maximal pro- $p$-quotient of the absolute Galois group $\tilde{G}:=\operatorname{Gal}(\bar{K} / K)$, char $K \neq p$. In fact Bogomolov in $[\mathrm{Bo}]$ and also Pop in lectures at MSRI in the fall of 1999, considered smaller Galois groups than the

Galois group defined above, namely the maximal pro-p-quotient of the group $\tilde{G} /[[\tilde{G}, \tilde{G}], \tilde{G}]$. In this paper we consider $p=2$, because of the connections with quadratic forms. It is expected however that a substantial part of our results can be extended to any prime $p$ provided that the base field $F$ contains a primitive $p$ th root of unity. We allow $F$ to be any field with char $F \neq 2$, and we are concerned with even smaller Galois groups than were considered by Bogomolov and Pop. Of course in this more general setting we cannot obtain as precise results as Bogomolov and Pop, but we do get some interesting information about the additive properties of multiplicative subgroups of fields. It would be very interesting to investigate further relationships between our work and the quoted work of Bogomolov, Pop and Tschinkel.
