Let $V, W$ be real vector spaces. It is shown that an odd mapping $f: V \rightarrow W$ satisfies $\sum_{i-1}^{2 n} f\left(x_{i}-\right.$ $\left.1 / 2 n \sum_{j=1}^{2 n} x_{j}\right)=\sum_{i=1}^{2 n} f\left(x_{i}\right)-2 n f\left(1 / 2 n \sum_{i=1}^{2 n} x_{i}\right)$ for all $x_{1}, \ldots, x_{2 n} \in V$ if and only if the odd mapping $f: V \rightarrow W$ is Cauchy additive. Furthermore, we prove the generalized Hyers-Ulam stability of the above functional equation in real Banach spaces.

## 1. Introduction

The stability problem of functional equations originated from a question of Ulam [1] concerning the stability of group homomorphisms. Hyers [2] gave the first affirmative partial answer to the question of Ulam for Banach spaces. Hyers' Theorem was generalized by Aoki [3] for additive mappings and by Th. M. Rassias [4] for linear mappings by considering an unbounded Cauchy difference. The paper of Th. M. Rassias [4] has provided a lot of influence in the development of what we call generalized Hyers-Ulam stability of functional equations. A generalization of Th. M. Rassias' theorem was obtained by Găvruta [5] by replacing the unbounded Cauchy difference by a general control function.

The functional equation,

$$
\begin{equation*}
f(x+y)+f(x-y)=2 f(x)+2 f(y), \tag{1.1}
\end{equation*}
$$

is called a quadratic functional equation. In particular, every solution of the quadratic functional equation is said to be a quadratic mapping. A generalized Hyers-Ulam stability problem for the
quadratic functional equation was proved by Skof [6] for mappings $f: X \rightarrow Y$, where $X$ is a normed space and $Y$ is a Banach space. Cholewa [7] noticed that the theorem of Skof is still true if the relevant domain $X$ is replaced by an Abelian group. The generalized Hyers-Ulam stability of the quadratic functional equation has been proved by Czerwik [8], J. M. Rassias [9], Găvruta [10], and others [11]. In [12], Th. M. Rassias proved that the norm defined over a real vector space $V$ is induced by an inner product if and only if for a fixed integer $n \geq 2$

$$
\begin{equation*}
\sum_{i=1}^{n}\left\|x_{i}-\frac{1}{n} \sum_{j=1}^{n} x_{j}\right\|^{2}=\sum_{i=1}^{n}\left\|x_{i}\right\|^{2}-n\left\|\frac{1}{n} \sum_{i=1}^{n} x_{i}\right\|^{2} \tag{1.2}
\end{equation*}
$$

holds for all $x_{1}, \ldots, x_{n} \in V$. An operator extension of this norm equality is presented in [13]. For more information on the recent results on the stability of quadratic functional equation, see [14]. Inner product spaces, Cauchy equation, Euler-Lagrange-Rassias equations, and Ulam-Găvruta-Rassias stability have been studied by several authors (see [15-27]).

In [28], C. Park, Lee, and Shin proved that if an even mapping $f: V \rightarrow W$ satisfies

$$
\begin{equation*}
\sum_{i=1}^{2 n} f\left(x_{i}-\frac{1}{2 n} \sum_{j=1}^{2 n} x_{j}\right)=\sum_{i=1}^{2 n} f\left(x_{i}\right)-2 n f\left(\frac{1}{2 n} \sum_{i=1}^{2 n} x_{i}\right) \tag{1.3}
\end{equation*}
$$

then the even mapping $f: V \rightarrow W$ is quadratic. Moreover, they proved the generalized Hyers-Ulam stability of the quadratic functional equation (1.3) in real Banach spaces.

Throughout this paper, assume that $n$ is a fixed positive integer, $X$ and $Y$ are real normed vector spaces.

In this paper, we investigate the functional equation

$$
\begin{equation*}
\sum_{i=1}^{2 n} f\left(x_{i}-\frac{1}{2 n} \sum_{j=1}^{2 n} x_{j}\right)=\sum_{i=1}^{2 n} f\left(x_{i}\right)-2 n f\left(\frac{1}{2 n} \sum_{i=1}^{2 n} x_{i}\right) \tag{1.4}
\end{equation*}
$$

and prove the generalized Hyers-Ulam stability of the functional equation (1.4) in real Banach spaces.

## 2. Functional Equations Related to Inner Product Spaces

We investigate the functional equation (1.4).
Lemma 2.1. Let $V$ and $W$ be real vector spaces. An odd mapping $f: V \rightarrow W$ satisfies

$$
\begin{equation*}
\sum_{i=1}^{2 n} f\left(x_{i}-\frac{1}{2 n} \sum_{j=1}^{2 n} x_{j}\right)=\sum_{i=1}^{2 n} f\left(x_{i}\right)-2 n f\left(\frac{1}{2 n} \sum_{i=1}^{2 n} x_{i}\right) \tag{2.1}
\end{equation*}
$$

for all $x_{1}, \ldots, x_{2 n} \in V$ if and only if the odd mapping $f: V \rightarrow W$ is Cauchy additive, that is,

$$
\begin{equation*}
f(x+y)=f(x)+f(y) \tag{2.2}
\end{equation*}
$$

for all $x, y \in V$.
Proof. Assume that $f: V \rightarrow W$ satisfies (2.1).
Letting $x_{1}=\cdots=x_{n}=x, x_{n+1}=\cdots=x_{2 n}=y$ in (2.1), we get

$$
\begin{equation*}
n f\left(x-\frac{x+y}{2}\right)+n f\left(y-\frac{x+y}{2}\right)=n f(x)+n f(y)-2 n f\left(\frac{x+y}{2}\right) \tag{2.3}
\end{equation*}
$$

for all $x, y \in V$. Since $f: V \rightarrow W$ is odd,

$$
\begin{equation*}
0=n f(x)+n f(y)-2 n f\left(\frac{x+y}{2}\right) \tag{2.4}
\end{equation*}
$$

for all $x, y \in V$ and $f(0)=0$. So

$$
\begin{equation*}
2 f\left(\frac{x+y}{2}\right)=f(x)+f(y) \tag{2.5}
\end{equation*}
$$

for all $x, y \in V$. Letting $y=0$ in (2.5), we get $2 f(x / 2)=f(x)$ for all $x \in V$. Thus

$$
\begin{equation*}
f(x+y)=2 f\left(\frac{x+y}{2}\right)=f(x)+f(y) \tag{2.6}
\end{equation*}
$$

for all $x, y \in V$.
It is easy to prove the converse.
For a given mapping $f: X \rightarrow Y$, we define

$$
\begin{equation*}
D f\left(x_{1}, \ldots, x_{2 n}\right):=\sum_{i=1}^{2 n} f\left(x_{i}-\frac{1}{2 n} \sum_{j=1}^{2 n} x_{j}\right)-\sum_{i=1}^{2 n} f\left(x_{i}\right)+2 n f\left(\frac{1}{2 n} \sum_{i=1}^{2 n} x_{i}\right) \tag{2.7}
\end{equation*}
$$

for all $x_{1}, \ldots, x_{2 n} \in X$.
We are going to prove the generalized Hyers-Ulam stability of the functional equation $D f\left(x_{1}, \ldots, x_{2 n}\right)=0$ in real Banach spaces.

Theorem 2.2. Let $f: X \rightarrow Y$ be a mapping satisfying $f(0)=0$ for which there exists a function $\varphi: X^{2 n} \rightarrow[0, \infty)$ such that

$$
\begin{gather*}
\tilde{\varphi}\left(x_{1}, \ldots, x_{2 n}\right):=\sum_{j=0}^{\infty} 2^{j} \varphi\left(\frac{x_{1}}{2^{j}}, \ldots, \frac{x_{2 n}}{2^{j}}\right)<\infty,  \tag{2.8}\\
\left\|D f\left(x_{1}, \ldots, x_{2 n}\right)\right\| \leq \varphi\left(x_{1}, \ldots, x_{2 n}\right) \tag{2.9}
\end{gather*}
$$

for all $x_{1}, \ldots, x_{2 n} \in X$. Then there exists a unique Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{equation*}
\|f(x)-f(-x)-A(x)\| \leq \frac{1}{n} \tilde{\varphi}(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{n} \tilde{\varphi}(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.10}
\end{equation*}
$$

for all $x \in X$.
Proof. Letting $x_{1}=\cdots=x_{n}=x$ and $x_{n+1}=\cdots=x_{2 n}=0$ in (2.9), we get

$$
\begin{equation*}
\left\|3 n f\left(\frac{x}{2}\right)+n f\left(\frac{-x}{2}\right)-n f(x)\right\| \leq \varphi(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.11}
\end{equation*}
$$

for all $x \in X$. Replacing $x$ by $-x$ in (2.11), we get

$$
\begin{equation*}
\left\|3 n f\left(\frac{-x}{2}\right)+n f\left(\frac{x}{2}\right)-n f(-x)\right\| \leq \varphi(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}), \tag{2.12}
\end{equation*}
$$

for all $x \in X$. Let $g(x):=f(x)-f(-x)$ for all $x \in X$. It follows from (2.11) and (2.12) that

$$
\begin{equation*}
\left\|2 n g\left(\frac{x}{2}\right)-n g(x)\right\| \leq \varphi(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\varphi(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.13}
\end{equation*}
$$

for all $x \in X$. So

$$
\begin{equation*}
\left\|g(x)-2 g\left(\frac{x}{2}\right)\right\| \leq \frac{1}{n} \varphi(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{n} \varphi(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.14}
\end{equation*}
$$

for all $x \in X$. Hence

$$
\begin{align*}
\left\|2^{l} g\left(\frac{x}{2^{l}}\right)-2^{m} g\left(\frac{x}{2^{m}}\right)\right\| \leq & \sum_{j=l}^{m-1} \frac{2^{j}}{n} \varphi(\underbrace{\frac{x}{2^{j^{\prime}}, \ldots, \frac{x}{2^{j}}},}_{n \text { times }} \underbrace{0, \ldots, 0}_{n \text { times }}) \\
& +\sum_{j=l}^{m-1} \frac{2^{j}}{n} \varphi(\underbrace{-\frac{x}{2^{j}}, \ldots,-\frac{x}{2^{j}}}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.15}
\end{align*}
$$

for all nonnegative integers $m$ and $l$ with $m>l$ and all $x \in X$. It follows from (2.8) and (2.15) that the sequence $\left\{2^{k} g\left(x / 2^{k}\right)\right\}$ is Cauchy for all $x \in X$. Since $Y$ is complete, the sequence $\left\{2^{k} g\left(x / 2^{k}\right)\right\}$ converges. So one can define the mapping $A: X \rightarrow Y$ by

$$
\begin{equation*}
A(x):=\lim _{k \rightarrow \infty} 2^{k} g\left(\frac{x}{2^{k}}\right) \tag{2.16}
\end{equation*}
$$

for all $x \in X$.
By (2.8) and (2.9),

$$
\begin{align*}
\left\|D A\left(x_{1}, \ldots, x_{2 n}\right)\right\| & =\lim _{k \rightarrow \infty} 2^{k}\left\|D g\left(\frac{x_{1}}{2^{k}}, \ldots, \frac{x_{2 n}}{2^{k}}\right)\right\| \\
& \leq \lim _{k \rightarrow \infty} 2^{k}\left[\varphi\left(\frac{x_{1}}{2^{k}}, \ldots, \frac{x_{2 n}}{2^{k}}\right)+\varphi\left(-\frac{x_{1}}{2^{k}}, \ldots,-\frac{x_{2 n}}{2^{k}}\right)\right]  \tag{2.17}\\
& =0
\end{align*}
$$

for all $x_{1}, \ldots, x_{2 n} \in X$. So $D A\left(x_{1}, \ldots, x_{2 n}\right)=0$. By Lemma 2.1, the mapping $A: X \rightarrow Y$ is Cauchy additive. Moreover, letting $l=0$ and passing the limit $m \rightarrow \infty$ in (2.15), we get (2.10). So there exists a Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) and (2.10).

Now, let $L: X \rightarrow Y$ be another Cauchy additive mapping satisfying (2.1) and (2.10). Then we have

$$
\begin{align*}
\|A(x)-L(x)\| & =2^{q}\left\|A\left(\frac{x}{2^{q}}\right)-L\left(\frac{x}{2^{q}}\right)\right\| \\
& \leq 2^{q}\left(\left\|A\left(\frac{x}{2^{q}}\right)-f\left(\frac{x}{2^{q}}\right)+f\left(\frac{-x}{2^{q}}\right)\right\|+\left\|L\left(\frac{x}{2^{q}}\right)-f\left(\frac{x}{2^{q}}\right)+f\left(\frac{-x}{2^{q}}\right)\right\|\right)  \tag{2.18}\\
& \leq \frac{2 \cdot 2^{q}}{n} \widetilde{\varphi}(\underbrace{\frac{x}{2^{q}}, \ldots, \frac{x}{2^{q}}}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{2 \cdot 2^{q}}{n} \tilde{\varphi}(\underbrace{\frac{-x}{2^{q}}, \ldots, \frac{-x}{2^{q}}}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}),
\end{align*}
$$

which tends to zero as $q \rightarrow \infty$ for all $x \in X$. So we can conclude that $A(x)=L(x)$ for all $x \in X$. This proves the uniqueness of $A$.

Corollary 2.3. Let $p>1$ and $\theta$ be positive real numbers, and let $f: X \rightarrow Y$ be a mapping such that

$$
\begin{equation*}
\left\|D f\left(x_{1}, \ldots, x_{2 n}\right)\right\| \leq \theta \sum_{j=1}^{2 n}\left\|x_{j}\right\|^{p} \tag{2.19}
\end{equation*}
$$

for all $x_{1}, \ldots, x_{2 n} \in X$. Then there exists a unique Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{equation*}
\|f(x)-f(-x)-A(x)\| \leq \frac{2^{p+1} \theta}{2^{p}-2}\|x\|^{p} \tag{2.20}
\end{equation*}
$$

for all $x \in X$.

Proof. Define $\varphi\left(x_{1}, \ldots, x_{2 n}\right)=\theta \sum_{j=1}^{2 n}\left\|x_{j}\right\|^{p}$, and apply Theorem 2.2 to get the desired result.

Corollary 2.4. Let $f: X \rightarrow Y$ be an odd mapping for which there exists a function $\varphi: X^{2 n} \rightarrow$ $[0, \infty)$ satisfying (2.8) and (2.9). Then there exists a unique Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{equation*}
\|2 f(x)-A(x)\| \leq \frac{1}{n} \tilde{\varphi}(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{n} \tilde{\varphi}(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}), \tag{2.21}
\end{equation*}
$$

or (alternative approximation)

$$
\begin{equation*}
\|f(x)-A(x)\| \leq \frac{1}{2 n} \tilde{\varphi}(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{2 n} \tilde{\varphi}(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.22}
\end{equation*}
$$

for all $x \in X$, where $\tilde{\varphi}$ is defined in (2.8).
Theorem 2.5. Let $f: X \rightarrow Y$ be a mapping satisfying $f(0)=0$ for which there exists a function $\varphi: X^{2 n} \rightarrow[0, \infty)$ satisfying (2.9) such that

$$
\begin{equation*}
\tilde{\varphi}\left(x_{1}, \ldots, x_{2 n}\right):=\sum_{j=1}^{\infty} 2^{-j} \varphi\left(2^{j} x_{1}, \ldots, 2^{j} x_{2 n}\right)<\infty \tag{2.23}
\end{equation*}
$$

for all $x_{1}, \ldots, x_{2 n} \in X$. Then there exists a unique Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{equation*}
\|f(x)-f(-x)-A(x)\| \leq \frac{1}{n} \tilde{\varphi}(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{n} \tilde{\varphi}(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.24}
\end{equation*}
$$

for all $x \in X$.
Proof. It follows from (2.13) that

$$
\begin{equation*}
\left\|g(x)-\frac{1}{2} g(2 x)\right\| \leq \frac{1}{2 n} \varphi(\underbrace{2 x, \ldots, 2 x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{2 n} \varphi(\underbrace{-2 x, \ldots,-2 x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.25}
\end{equation*}
$$

for all $x \in X$. So

$$
\begin{align*}
\left\|\frac{1}{2^{l}} g\left(2^{l} x\right)-\frac{1}{2^{m}} g\left(2^{m} x\right)\right\| \leq & \sum_{j=l+1}^{m} \frac{1}{2^{j} n} \varphi(\underbrace{2^{j} x, \ldots, 2^{j} x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \\
& +\sum_{j=l+1}^{m} \frac{1}{2^{j} n} \varphi(\underbrace{-2^{j} x, \ldots,-2^{j} x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.26}
\end{align*}
$$

for all nonnegative integers $m$ and $l$ with $m>l$ and all $x \in X$. It follows from (2.23) and (2.26) that the sequence $\left\{\left(1 / 2^{k}\right) g\left(2^{k} x\right)\right\}$ is Cauchy for all $x \in X$. Since $Y$ is complete, the sequence $\left\{\left(1 / 2^{k}\right) g\left(2^{k} x\right)\right\}$ converges. So one can define the mapping $A: X \rightarrow Y$ by

$$
\begin{equation*}
A(x):=\lim _{k \rightarrow \infty} \frac{1}{2^{k}} g\left(2^{k} x\right) \tag{2.27}
\end{equation*}
$$

for all $x \in X$.
By (2.9) and (2.23),

$$
\begin{align*}
\left\|D A\left(x_{1}, \ldots, x_{2 n}\right)\right\| & =\lim _{k \rightarrow \infty} \frac{1}{2^{k}}\left\|D g\left(2^{k} x_{1}, \ldots, 2^{k} x_{2 n}\right)\right\| \\
& \leq \lim _{k \rightarrow \infty} \frac{1}{2^{k}}\left(\varphi\left(2^{k} x_{1}, \ldots, 2^{k} x_{2 n}\right)+\varphi\left(-2^{k} x_{1}, \ldots,-2^{k} x_{2 n}\right)\right)  \tag{2.28}\\
& =0
\end{align*}
$$

for all $x_{1}, \ldots, x_{2 n} \in X$. So $D A\left(x_{1}, \ldots, x_{2 n}\right)=0$. By Lemma 2.1, the mapping $A: X \rightarrow Y$ is Cauchy additive. Moreover, letting $l=0$ and passing the limit $m \rightarrow \infty$ in (2.26), we get (2.24). So there exists a Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) and (2.24).

The rest of the proof is similar to the proof of Theorem 2.2.
Corollary 2.6. Let $p<1$ and $\theta$ be positive real numbers, and let $f: X \rightarrow Y$ be a mapping satisfying (2.19). Then there exists a unique Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{equation*}
\|f(x)-f(-x)-A(x)\| \leq \frac{2^{p+1} \theta}{2-2^{p}}\|x\|^{p} \tag{2.29}
\end{equation*}
$$

for all $x \in X$.
Proof. Define $\varphi\left(x_{1}, \ldots, x_{2 n}\right)=\theta \sum_{j=1}^{2 n}\left\|x_{j}\right\|^{p}$, and apply Theorem 2.5 to get the desired result.

Corollary 2.7. Let $f: X \rightarrow Y$ be an odd mapping for which there exists a function $\varphi: X^{2 n} \rightarrow$ $[0, \infty)$ satisfying (2.9) and (2.23). Then there exists a unique Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{equation*}
\|2 f(x)-A(x)\| \leq \frac{1}{n} \tilde{\varphi}(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{n} \tilde{\varphi}(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.30}
\end{equation*}
$$

or (alternative approximation),

$$
\begin{equation*}
\|f(x)-A(x)\| \leq \frac{1}{2 n} \tilde{\varphi}(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{2 n} \tilde{\varphi}(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.31}
\end{equation*}
$$

for all $x \in X$, where $\tilde{\varphi}$ is defined in (2.23).
The following was proved in [28].
Remark 2.8 ([28]). Let $f: X \rightarrow Y$ be a mapping satisfying $f(0)=0$ for which there exists a function $\varphi: X^{2 n} \rightarrow[0, \infty)$ satisfying (2.9) such that

$$
\begin{equation*}
\Phi\left(x_{1}, \ldots, x_{2 n}\right):=\sum_{j=0}^{\infty} 4^{j} \varphi\left(\frac{x_{1}}{2^{j}}, \ldots, \frac{x_{2 n}}{2^{j}}\right)<\infty \tag{2.32}
\end{equation*}
$$

for all $x_{1}, \ldots, x_{2 n} \in X$. Then there exists a unique quadratic mapping $Q: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{equation*}
\|f(x)+f(-x)-Q(x)\| \leq \frac{1}{n} \Phi(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{n} \Phi(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.33}
\end{equation*}
$$

for all $x \in X$.
Note that

$$
\begin{equation*}
\sum_{j=0}^{\infty} 2^{j} \varphi\left(\frac{x_{1}}{2^{j}}, \ldots, \frac{x_{2 n}}{2^{j}}\right) \leq \sum_{j=0}^{\infty} 4^{j} \varphi\left(\frac{x_{1}}{2^{j}}, \ldots, \frac{x_{2 n}}{2^{j}}\right) \tag{2.34}
\end{equation*}
$$

Combining Theorem 2.2 and Remark 2.8, we obtain the following result.
Theorem 2.9. Let $f: X \rightarrow Y$ be a mapping satisfying $f(0)=0$ for which there exists a function $\varphi: X^{2 n} \rightarrow[0, \infty)$ satisfying (2.9) and (2.32). Then there exist a unique Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) and a unique quadratic mapping $Q: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{align*}
\|2 f(x)-A(x)-Q(x)\| \leq & \frac{1}{n} \tilde{\varphi}(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{n} \tilde{\varphi}(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \\
& +\frac{1}{n} \Phi(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{n} \Phi(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.35}
\end{align*}
$$

for all $x \in X$, where $\tilde{\varphi}$ and $\Phi$ are defined in (2.8) and (2.32), respectively.
Corollary 2.10. Let $p>2$ and $\theta$ be positive real numbers, and let $f: X \rightarrow Y$ be a mapping satisfying (2.19). Then there exist a unique Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) and a unique quadratic mapping $Q: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{equation*}
\|2 f(x)-A(x)-Q(x)\| \leq\left(\frac{2^{p+1}}{2^{p}-2}+\frac{2^{p+1}}{2^{p}-4}\right) \theta\|x\|^{p} \tag{2.36}
\end{equation*}
$$

for all $x \in X$.
Proof. Define $\varphi\left(x_{1}, \ldots, x_{2 n}\right)=\theta \sum_{j=1}^{2 n}\left\|x_{j}\right\|^{p}$, and apply Theorem 2.9 to get the desired result.

The following was proved in [28].
Remark 2.11 (see [28]). Let $f: X \rightarrow Y$ be a mapping satisfying $f(0)=0$ for which there exists a function $\varphi: X^{2 n} \rightarrow[0, \infty)$ satisfying (2.9) such that

$$
\begin{equation*}
\Phi\left(x_{1}, \ldots, x_{2 n}\right):=\sum_{j=1}^{\infty} 4^{-j} \varphi\left(2^{j} x_{1}, \ldots, 2^{j} x_{2 n}\right)<\infty \tag{2.37}
\end{equation*}
$$

for all $x_{1}, \ldots, x_{2 n} \in X$. Then there exists a unique quadratic mapping $Q: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{equation*}
\|f(x)+f(-x)-Q(x)\| \leq \frac{1}{n} \Phi(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{n} \Phi(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \tag{2.38}
\end{equation*}
$$

for all $x \in X$.

Note that

$$
\begin{equation*}
\sum_{j=1}^{\infty} 4^{-j} \varphi\left(2^{j} x_{1}, \ldots, 2^{j} x_{2 n}\right) \leq \sum_{j=1}^{\infty} 2^{-j} \varphi\left(2^{j} x_{1}, \ldots, 2^{j} x_{2 n}\right) . \tag{2.39}
\end{equation*}
$$

Combining Theorem 2.5 and Remark 2.11, we obtain the following result.
Theorem 2.12. Let $f: X \rightarrow Y$ be a mapping satisfying $f(0)=0$ for which there exists a function $\varphi: X^{2 n} \rightarrow[0, \infty)$ satisfying (2.9) and (2.23). Then there exist a unique Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) and a unique quadratic mapping $Q: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{align*}
\|2 f(x)-A(x)-Q(x)\| \leq & \frac{1}{n} \tilde{\varphi}(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{n} \tilde{\varphi}(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}) \\
& +\frac{1}{n} \Phi(\underbrace{x, \ldots, x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }})+\frac{1}{n} \Phi(\underbrace{-x, \ldots,-x}_{n \text { times }}, \underbrace{0, \ldots, 0}_{n \text { times }}), \tag{2.40}
\end{align*}
$$

for all $x \in X$, where $\tilde{\varphi}$ and $\Phi$ are defined in (2.23) and (2.37), respectively.
Corollary 2.13. Let $p<1$ and $\theta$ be positive real numbers, and let $f: X \rightarrow Y$ be a mapping satisfying (2.19). Then there exist a unique Cauchy additive mapping $A: X \rightarrow Y$ satisfying (2.1) and a unique quadratic mapping $Q: X \rightarrow Y$ satisfying (2.1) such that

$$
\begin{equation*}
\|2 f(x)-A(x)-Q(x)\| \leq\left(\frac{2^{p+1}}{2-2^{p}}+\frac{2^{p+1}}{4-2^{p}}\right) \theta\|x\|^{p}, \tag{2.41}
\end{equation*}
$$

for all $x \in X$.
Proof. Define $\varphi\left(x_{1}, \ldots, x_{2 n}\right)=\theta \sum_{j=1}^{2 n}\left\|x_{j}\right\|^{p}$, and apply Theorem 2.12 to get the desired result.
