Chebyshev type inequality, Convex cone, Dual cone, Orthoprojector.
The aim of this note is to give a general framework for Chebyshev inequalities and other classic inequalities. Some applications to Chebyshev inequalities are made. In addition, the relations of similar ordering, monotonicity in mean and synchronicity of vectors are discussed.

## 1. Introduction and summary

Let $V$ be a real vector space provided with an inner product $\langle\cdot, \cdot\rangle$. For fixed $x \in V$ and $y, z \in V$ the inequality

$$
\begin{equation*}
\langle x, y\rangle\langle x, z\rangle \leq\langle y, z\rangle\langle x, x\rangle \tag{1.1}
\end{equation*}
$$

is called a Chebyshev type inequality.
A general method for finding vectors satisfying the above inequality is given by Niezgoda in [4]. The same author in [3] proved a projection inequality for the Eaton system, obtaining a Chebyshev type inequality as a particular case for orthoprojectors of rank one. Furthermore, the relation of synchronicity with respect to the Eaton system is introduced there. It generalizes commonly known relations of similarly ordered vectors (cf. for example, [6, chap. 7.1]).

This paper is organized as follows. Section 2 contains basic notions related to convex cones. In Section 3 a projection inequality in an abstract Hilbert space is studied. The framework covers the projection inequality for the Eaton system, Chebyshev sum and integral inequalities and others, see Examples 3.1-3.3. We modify and extend the applicability of the relation of synchronicity to vector spaces with infinite bases. The results are applied to the Chebyshev sum inequality in Section 4 and the Chebyshev integral inequality in Section 5.

## 2. Preliminaries

In this note $V$ is a real Hilbert space with an inner product $\langle\cdot, \cdot\rangle$. A convex cone is a nonempty set $D \subset V$ such that $\alpha D+\beta D \subset D$ for all nonnegative scalars $\alpha$ and $\beta$. The closure of the convex cone of all nonnegative finite combinations in $H \subset V$ is denoted by cone $H$. Similarly, span $H$ denotes the closure of the subspace of all finite combinations in $H$. The dual cone of a subset $C \subset V$ is defined as follows

$$
\text { dual } C=\{v \in V:\langle v, C\rangle \geq 0\}
$$

It is known, that the dual cone of $C$ is a closed convex cone and

$$
\operatorname{dual} C=\operatorname{dual}(\operatorname{cone} C)
$$

If for a subset $G \subset V$, a closed convex cone $C$ is equal to cone $G$, then we say that $C$ is generated by $G$ or $G$ is a generator of $C$. The inclusion $A \subset B$ implies dual $B \subset$ dual $A$. If $C$ and $D$ are convex cones, then

$$
\operatorname{dual}(C+D)=\text { dual } C \cap \text { dual } D
$$

The dual cone of a subspace $W$ is equal to its orthogonal complement $W^{\perp}$. If a set $C$ is a closed convex cone, then

$$
\text { dual dual } C=C \text {, }
$$

(cf. [5, lemma 2.1]). The symbol dual ${ }_{V_{1}} C$ stands for $V_{1} \cap$ dual $C$ and means the relative dual of $C$ with respect to a closed subspace $V_{1}$ of $V$. If for a closed convex cone $D$ the identity dual $V_{1} D=D$ holds, then $D$ is called a self-dual cone w.r.t. $V_{1}$. For example, the convex cone generated by an orthogonal system of vectors is self-dual w.r.t. the subspace spanned by this system.

In other cases the standard mathematical notation is used.

## 3. Projection Inequality

From now on we make the following assumptions: $P$ is an idempotent and symmetric operator (orthoprojector) defined on $V, V=V_{1}+V_{2}$, where $V_{1}$ is the range of $P$ and $V_{2}$ is its orthogonal complement, i.e. $V_{1}=P V$ and $V_{2}=(P V)^{\perp}$. The identity operator is denoted by id. All subspaces and convex cones of a real Hilbert space $V$ are assumed to be closed.

For $y, z \in V$ we will consider a projection inequality (briefly (PI)) of the form

$$
\langle y, P z\rangle \geq 0
$$

If $y=z$, then (PI) holds for any orthoprojector $P$ taking the form $\|P z\|^{2} \geq 0$. A general method of solution of (PI) is established by our following theorem (cf. [4, Theorem 3.1]).

Theorem 3.1. For vectors $y, z \in V$ and a convex cone $C \subset V$ the following statements are mutually equivalent.
i) (PI) holds for all $y \in C+V_{2}$
ii) $P z \in$ dual $C$
iii) $z \in$ dual $P C$.

Proof. Since i), the inequality (PI) holds for every $y \in C$. Thus

$$
0 \leq\langle y, P z\rangle=\langle P y, z\rangle
$$

Therefore $0 \leq\langle C, P z\rangle=\langle P C, z\rangle$. Hence $P z \in \operatorname{dual} C$ and $z \in$ dual $P C$. It proves that i) $\Rightarrow$ ii), iii).

Conversely, if $P z \in$ dual $C$ then for $y=c+x$, where $c \in C$ and $\left\langle x, V_{1}\right\rangle=$ 0 are arbitrary have $\langle y, P z\rangle=\langle c, P z\rangle+\langle x, P z\rangle=\langle c, P z\rangle \geq 0$. By a similar

Chebyshev Inequalities and Self-Dual Cones

argument, if $z \in$ dual $P C$ then $y \in C+V_{2}$ implies that $P y \in P C$. It leads to $\langle y, P z\rangle=\langle P y, z\rangle \geq 0$. From this we conclude that ii),iii) $\Rightarrow$ i), which completes the proof.

Example 3.1 (Bessel inequality). For an orthoprojector $P$ the inequality (PI) holds provided that $y=z$. Let $\left\{f_{\nu}\right\}$ be an orthogonal system in $V$. If $P$ is the orthoprojector onto the subspace orthogonal to span $\left\{f_{\nu}\right\}$, i.e. $P=\mathrm{id}-\sum_{\nu} \frac{\left\langle\cdot, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|^{2}} f_{\nu}$, then we obtain the classic Bessel inequality

$$
\|z\|^{2} \geq \sum_{\nu} \frac{\left\langle z, f_{\nu}\right\rangle^{2}}{\left\|f_{\nu}\right\|^{2}}
$$

Example 3.2 (Chebyshev type inequalities). Let $x \in V$ be a fixed nonzero vector. Set $P=\mathrm{id}-\frac{\langle, x\rangle}{\|x\|^{2}} x$. It is clear that $P$ is the orthoprojector onto the subspace orthogonal to $x$. In the case where the inequality (PI) becomes a Chebyshev type inequality (1.1):

$$
\langle x, z\rangle\langle y, x\rangle \leq\langle y, z\rangle\|x\|^{2} .
$$

In the space $V=\mathbb{R}^{n}$ under $x=(1, \ldots, 1)$, inequality (1.1) transforms into the Chebyshev sum inequality (or (CHSI) for short):

$$
\sum_{i=1}^{n} y_{i} \sum_{i=1}^{n} z_{i} \leq n \sum_{i=1}^{n} y_{i} z_{i} .
$$

Consider the space $V=L^{2}$ of all 2-nd power integrable functions with respect to the Lebesgue measure $\mu$ on the unit interval $[0,1]$. For $x \equiv 1$ inequality (1.1) takes the form of a Chebeshev integral inequality (or (CHII) for short):

$$
\int y d \mu \int z d \mu \leq \int y z d \mu
$$

Example 3.3 (Projection inequality for Eaton systems). Let $G$ be a closed subgroup of the orthogonal group acting on $V, \operatorname{dim} V<\infty$, and $C \subset V$ be a closed convex cone. Let us assume:
i) for each vector $a \in V$ there exist $g \in G$ and $b \in C$ satisfying $a=g b$,
ii) $\langle a, g b\rangle \leq\langle a, b\rangle$ for all $a, b \in C$ and $g \in G$.

If $P$ is the orthoprojector onto a subspace orthogonal to $\{a \in V: G a=a\}$, then the inequality (PI) holds, provided that $y, z \in C$, (cf. [3, Theorem 2.1]).

The triplet ( $V, G, C$ ) fulfiling the conditions i)-ii) is said to be an Eaton system, (see e.g. [3] and the references given therein). The main example of this structure is the permutation group acting on $\mathbb{R}^{n}$ and the cone of nonincreasing vectors.

Let $C \subset V$ be a convex cone. Every cone of the form $C+V_{2}$ has the representation:

$$
\begin{equation*}
C+V_{2}=P C+V_{2} . \tag{3.1}
\end{equation*}
$$

Therefore, on studying the projection inequality (PI), according to Theorem 3.1, it is sufficient to consider convex cones of the form $C=D+V_{2}$, where $D$ is a convex cone in $V_{1}$. The following proposition is a simple consequence of Theorem 3.1.

Proposition 3.2. Let $D \subset V_{1}$ be a convex cone. For $y, z \in V$ the following conditions are equivalent.
i) (PI) holds for all $y \in D+V_{2}$
ii) $z \in \operatorname{dual} D$.

Let $D \subset V_{1}$ be a convex cone. Then $V_{2} \subset$ dual $D$. This implies that $P$ dual $D=$ $V_{1} \cap$ dual $D$. Applying (3.1) to dual $D+V_{2}=\operatorname{dual} D$, we get

$$
\begin{equation*}
\text { dual }_{V_{1}} D+V_{2}=\text { dual } D . \tag{3.2}
\end{equation*}
$$

According to the above equation and the last proposition, we need to find for (PI) such cones $D$ for which $D \cap$ dual $_{V_{1}} D$ are as wide as possible.

Proposition 3.3. The inequality (PI) holds for $y, z \in D+V_{2}$, where $D$ is an arbitrary self-dual cone w.r.t. $V_{1}$.

Proof. By assumption, $D \subset V_{1}$, hence (3.2) gives dual $D=D+V_{2}$. Proposition 3.2 implies that (PI) holds for $y, z \in\left(D+V_{2}\right) \cap$ dual $D=D+V_{2}$.

If $D$ is a self-dual cone w.r.t. $V_{1}$ then $D+V_{2}$ is a maximal cone for (PI) in the following sense.

Proposition 3.4. Let $D$ be a self-dual cone w.r.t. $V_{1}$ with $D+V_{2} \subset C$, where $C \subset V$ is a convex cone.

If (PI) holds for $y, z \in C$ then $C=D+V_{2}$.
Proof. Since $V_{2} \subset C$, (3.1) yields $C=P C+V_{2}$. By Proposition 3.2, (PI) holds for $y, z \in\left(P C+V_{2}\right) \cap$ dual $P C$. The assumption that (PI) holds for $y, z \in C$ gives $P C+V_{2} \subset$ dual $P C$. Since $D+V_{2} \subset C, D=P\left(D+V_{2}\right) \subset P C$. From this we have dual $P C \subset$ dual $D=D+V_{2}$, by (3.2), because dual ${ }_{V_{1}} D=D$. Combining these inclusions we can see that $C=P C+V_{2} \subset D+V_{2}$.

The converse inclusion holds by the hypothesis, and thus the proof is complete.

Let $G_{P}$ denote the set of all unitary operators acting on $V$ with $g V_{2}=V_{2}$. Notice that $G_{P}$ is a group of operators. The inequality (PI) is invariant with respect to $G_{P}$.

Theorem 3.5. For fixed $g \in G_{P}$ the following statements are equivalent.
i) (PI) holds for $y, z$
ii) (PI) holds for gy, gz.

Proof. Assume that $g$ is a unitary operator satisfying $g V_{2}=V_{2}$. This is equivalent to $g^{*} V_{2}=V_{2}$, where $g^{*}$ is the adjoint operator of $g$. We first show that $g V_{1} \subset V_{1}$.

Suppose, contrary to our claim, that there exists a $u \in V_{1}$ with the property $g u=v_{1}+v_{2}, v_{i} \in V_{i}, i=1,2, v_{2} \neq 0$. We have:

$$
\begin{aligned}
\|u\|^{2}=\|g u\|^{2}=\| v_{1} & +v_{2}\left\|^{2}=\right\| v_{1}\left\|^{2}+\right\| v_{2} \|^{2} \quad\left(g-\text { unitary }, v_{1} \perp v_{2}\right) \\
\left\|u-g^{*} v_{2}\right\|^{2} & =\left\|g\left(u-g^{*} v_{2}\right)\right\|^{2} \\
& =\left\|g u-v_{2}\right\|^{2} \\
& =\left\|v_{1}\right\|^{2} \quad\left(\text { since } g-\text { unitary }, g^{*} g=\mathrm{id}\right) \\
\left\|u-g^{*} v_{2}\right\|^{2} & =\|u\|^{2}+\left\|g^{*} v_{2}\right\|^{2} \\
& =\|u\|^{2}+\left\|v_{2}\right\|^{2} \quad\left(u \perp g^{*} v_{2}, g^{*}-\text { unitary }\right) .
\end{aligned}
$$

Hence:

$$
\left\{\begin{array}{l}
\|u\|^{2}=\left\|v_{1}\right\|^{2}+\left\|v_{2}\right\|^{2} \\
\left\|v_{1}\right\|^{2}=\|u\|^{2}+\left\|v_{2}\right\|^{2}
\end{array} \Rightarrow\left\|v_{2}\right\|^{2}=0 \Rightarrow v_{2}=0\right.
$$

a contradiction. This completes the proof of $g V_{1} \subset V_{1}$.
Note that $g^{*} V_{1} \subset V_{1}$, too. This implies that $V_{1} \subset g V_{1}$. Therefore

$$
\begin{equation*}
g V_{1}=V_{1} . \tag{3.3}
\end{equation*}
$$

Now, let $z \in V$ be arbitrary. We have $z=z_{1}+z_{2}$, where $z_{i} \in V_{i}, i=1,2$. For an orthoprojector $P$ onto $V_{1}$ we get:

$$
g P z=g P\left(z_{1}+z_{2}\right)=g z_{1}=P\left(g z_{1}+g z_{2}\right)=P g z,
$$

because $g z_{1} \in V_{1}$ by (3.3) and $g z_{2} \in V_{2}$ by assumption. Thus

$$
\begin{equation*}
P g=g P . \tag{3.4}
\end{equation*}
$$

By (3.4),

$$
\langle g y, P g z\rangle=\langle g y, g P z\rangle=\left\langle g^{*} g y, P z\right\rangle=\langle y, P z\rangle .
$$

This proves required equivalence.
A simple consequence of the above theorem is:
Remark 1. For a convex cone $C \subset V$ and $g_{0} \in G_{P}$ the following statements are equivalent.
i) (PI) holds for $y, z \in C$
ii) (PI) holds for $y, z \in g_{0} C$.

In the remainder of this section we assume that $V$ is a real separable Hilbert space.
Let $\left\{f_{\nu}\right\}$ be an orthogonal basis of $V_{1}$, i.e.

$$
\left\langle f_{\eta}, f_{\nu}\right\rangle \begin{cases}>0, & \eta=\nu \\ =0, & \eta \neq \nu\end{cases}
$$

for integers $\eta, \nu$.
Under the above assumption, the projection $P z$ takes the form:

$$
\begin{equation*}
P z=\sum_{\nu} \frac{\left\langle z, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|^{2}} f_{\nu} \tag{3.5}
\end{equation*}
$$

Chebyshev Inequalities and Self-Dual Cones

issn: 1443-575b

From this, for $y, z \in V$ we have

$$
\langle y, P z\rangle=\sum_{\nu} \frac{\left\langle y, f_{\nu}\right\rangle\left\langle z, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|^{2}}
$$

Therefore the following remark is evident.
Remark 2. Let $\left\{f_{\nu}\right\}$ be an orthogonal basis of $V_{1}$.
For $y, z \in V$ the inequality (PI) holds if and only if

$$
\sum_{\nu} \frac{\left\langle y, f_{\nu}\right\rangle\left\langle z, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|^{2}} \geq 0
$$

Set

$$
\begin{equation*}
D=\left\{x \in V: x=\sum_{\nu} \alpha_{\nu} f_{\nu}, \alpha_{\nu} \geq 0\right\} \tag{3.6}
\end{equation*}
$$

Clearly, $D$ is a closed convex cone generated by the system $\left\{f_{\nu}\right\}$. The scalars $\alpha_{\nu}=$ $\frac{\left\langle x, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|^{2}}$ are the Fourier coefficients of $x$ w.r.t. the orthogonal system $\left\{f_{\nu}\right\}$. Moreover, $D$ is a self-dual cone w.r.t. $V_{1}$. By Proposition 3.3 we get

Corollary 3.6. If $\left\{f_{\nu}\right\}$ is an orthogonal basis of $V_{1}$, then (PI) holds for $y, z \in D+V_{2}$, where $D$ is defined by (3.6).

Let $\Xi$ denote the set of all sequences $\xi=\left(\xi_{1}, \xi_{2}, \ldots\right)$ with $\xi_{\nu}^{2}=1, \nu=1,2, \ldots$. For given $\xi$, let us define the operator $g_{\xi}$ on $V$ as follows:

$$
g_{\xi} x=x-P x+\sum_{\nu} \xi_{\nu} \frac{\left\langle x, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|^{2}} f_{\nu}
$$

Chebyshev Inequalities and Self-Dual Cones

This operator is an isometry, because

$$
\begin{aligned}
\left\|g_{\xi} x\right\|^{2} & =\|x\|^{2}-\|P x\|^{2}+\sum_{\nu} \xi_{\nu}^{2} \frac{\left\langle x, f_{\nu}\right\rangle^{2}}{\left\|f_{\nu}\right\|^{2}} \\
& =\|x\|^{2}-\|P x\|^{2}+\|P x\|^{2}=\|x\|^{2}
\end{aligned}
$$

by (3.5) and obvious orthogonality

$$
x-P x \perp \sum_{\nu} \xi_{\nu} \frac{\left\langle x, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|^{2}} f_{\nu} .
$$

Zdzisław Otachel
vol. 10, iss. 2, art. 54, 2009

If $x \in V_{2}$, then $\left\langle x, f_{\nu}\right\rangle=0$ for all $\nu$. Hence $P x=0=\sum_{\nu} \xi_{\nu} \frac{\left\langle x, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|^{2}} f_{\nu}$. For this reason

$$
\begin{equation*}
g_{\xi} x=x, \quad x \in V_{2} . \tag{3.7}
\end{equation*}
$$

We write

$$
\begin{equation*}
G=\left\{g_{\xi}: \xi \in \Xi\right\} . \tag{3.8}
\end{equation*}
$$

We will show that $G$ is a group of operators. It is evident that:

$$
\begin{equation*}
g_{\xi}=\mathrm{id}, \quad \text { for } \xi=(1,1, \ldots) . \tag{3.9}
\end{equation*}
$$

Let $\zeta, \xi, \gamma \in \Xi$. We have:

$$
g_{\zeta} f_{\nu}=f_{\nu}-P f_{\nu}+\sum_{\eta} \zeta_{\eta} \frac{\left\langle f \nu, f_{\eta}\right\rangle}{\left\|f_{\eta}\right\|^{2}} f_{\eta}=\zeta_{\nu} f \nu
$$

Title Page
Contents

Page 12 of 31
Go Back
Full Screen
Close
journal of inequalities in pure and applied mathematics
issn: 1443-575b
because $P f_{\nu}=f_{\nu}, \nu=1,2, \ldots$. From this, by $x-P x \in V_{2}$ and (3.7) we get:

$$
\begin{aligned}
g_{\zeta} g_{\xi} x & =g_{\zeta}\left(x-P x+\sum_{\nu} \xi_{\nu} \frac{\left\langle x, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|^{2}} f_{\nu}\right) \\
& =g_{\zeta}(x-P x)+\sum_{\nu} \xi_{\nu} \frac{\left\langle x, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|^{2}} g_{\zeta} f_{\nu} \\
& =x-P x+\sum_{\nu} \zeta_{\nu} \xi_{\nu} \frac{\left\langle x, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|^{2}} f_{\nu} .
\end{aligned}
$$

Thus

$$
\begin{equation*}
g_{\zeta} g_{\xi}=g_{\zeta \cdot \xi}=g_{\xi} g_{\zeta} \tag{3.10}
\end{equation*}
$$

where $\zeta \cdot \xi=\left(\zeta_{1} \xi_{1}, \zeta_{2} \xi_{2}, \ldots\right)$. This clearly gives:

$$
\begin{equation*}
g_{\zeta}\left(g_{\xi} g_{\gamma}\right)=g_{\zeta \cdot \xi \cdot \gamma}=\left(g_{\xi} g_{\zeta}\right) g_{\gamma} \tag{3.11}
\end{equation*}
$$

and

$$
g_{\xi} g_{\xi}=g_{\xi \cdot \xi}=\mathrm{id}
$$

which is equivalent to

$$
\begin{equation*}
\left(g_{\xi}\right)^{-1}=g_{\xi} \tag{3.12}
\end{equation*}
$$

Since $g_{\xi}$ is an isometry and invertible,

$$
\begin{equation*}
g_{\xi}-\text { unitary }, \quad \forall_{\xi \in \Xi} . \tag{3.13}
\end{equation*}
$$

By (3.13), (3.7), (3.9) - (3.12) we can assert that $G$ is an Abelian group of unitary operators that are identities on $V_{2}$. As a consequence, $G \subset G_{P}$.

Chebyshev Inequalities and Self-Dual Cones

Given any $x \in V$, we define $\xi_{x}=\left(\xi_{x, 1}, \xi_{x, 2}, \ldots\right)$ by

$$
\xi_{x, \nu}=\left\{\begin{align*}
1, & \left\langle x, f_{\nu}\right\rangle \geq 0  \tag{3.14}\\
-1, & \left\langle x, f_{\nu}\right\rangle<0
\end{align*}\right.
$$

It is clear that $\xi_{x, \nu}\left\langle x, f_{\nu}\right\rangle=\left|\left\langle x, f_{\nu}\right\rangle\right|$. Hence

$$
g_{\xi_{x}} x=x-P x+\sum_{\nu} \frac{\left|\left\langle x, f_{\nu}\right\rangle\right|}{\left\|f_{\nu}\right\|^{2}} f_{\nu},
$$

where $x-P x \in V_{2}$ and $\sum_{\nu} \frac{\left|\left\langle x, f_{\nu}\right\rangle\right|}{\left\|f_{\nu}\right\|^{2}} f_{\nu} \in D$. Therefore

$$
\begin{equation*}
g_{\xi_{x}} x \in D+V_{2} . \tag{3.15}
\end{equation*}
$$

Assertion (3.15) is simply the statement that

$$
\begin{equation*}
(G x) \cap C \neq \emptyset, \quad \forall_{x \in V} \tag{3.16}
\end{equation*}
$$

with $C=D+V_{2}$. This condition ensures that the sum of the cones $g C$, where $g$ runs over $G$, covers the whole space $V$. Now, we show that (3.16) holds for $G_{P}$ and for every cone $C=P C+V_{2}, P C \neq\{0\}$.

Fix $v \in V$. Clearly, $v=v_{1}+v_{2}, v_{i} \in V_{i}, i=1,2$. If $v_{1}=0$ then $v \in$ $G_{P} v \subset V_{2} \subset C$, i.e. (3.16) holds. Assume that $0 \neq v_{1}$ and note that there exists $0 \neq u_{1} \in P C$. Let us construct the two orthogonal bases $\left\{e_{\nu}\right\}$ and $\left\{f_{\nu}\right\}$ of $V_{1}$ with $e_{1}=v_{1}$ and $f_{1}=u_{1}$. Set $u=\left\|v_{1}\right\| \frac{u_{1}}{\left\|u_{1}\right\|}+v_{2}$ and

$$
\begin{equation*}
g=\operatorname{id}-P+\sum_{\nu} \frac{\left\langle\cdot, e_{\nu}\right\rangle}{\left\|e_{\nu}\right\|\left\|f_{\nu}\right\|} f_{\nu} . \tag{3.17}
\end{equation*}
$$

Observe that $u \in C, g v=u$ and $g$ is the identity operator on $V_{2}$. Now, we prove that $g$ is unitary. Firstly, we note that for any $x \in V$

$$
\|g x\|^{2}=\|x\|^{2}-\|P x\|^{2}+\sum_{\nu} \frac{\left\langle x, e_{\nu}\right\rangle^{2}}{\left\|e_{\nu}\right\|^{2}}=\|x\|^{2}
$$

because $\|P x\|^{2}=\sum_{\nu} \frac{\left\langle x, e_{\nu}\right\rangle^{2}}{\left\|e_{\nu}\right\|^{2}}$. Our next goal is to show that $g V=V$. To do this, fix $y \in V$. We have

$$
y=y-P y+\sum_{\nu} \frac{\left\langle y, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|} \frac{f_{\nu}}{\left\|f_{\nu}\right\|}
$$

Set

$$
x=y-P y+\sum_{\nu} \frac{\left\langle y, f_{\nu}\right\rangle}{\left\|f_{\nu}\right\|} \frac{e_{\nu}}{\left\|e_{\nu}\right\|}
$$

It is easily seen that $g x=y$. So, $g$ is unitary.
Finally, $g$ is a unitary operator on $V$ with $g V_{2}=V_{2}$ and $g v=u$. It gives $u \in$ $G_{P} \cup \cap C$, as desired.

We are now in a position to introduce a notion of synchronicity of vectors for (PI). For an orthoprojector $P$ let $C$ be a convex cone which admits the representation

$$
C=P C+V_{2},
$$

where $P C$ is nontrivial. Let $G$ be a subgroup of $G_{P}$ with the property (3.16).
The two vectors $y, z \in V$ are said to be $G$-synchronous (with respect to $C$ ) if there exists a $g \in G$ such that $g y, g z \in C$. If $G=G_{P}$, then we simply say that $y$ and $z$ are synchronous.

The definition is motivated by [3, sec. 2]. It generalizes the notion of synchronicity with respect to Eaton systems. Obviously, $G$-synchronicity forces synchronicity

under fixed $C$. In the sequel, for special cones we show that synchronicity is equivalent to (PI) but $G$-synchronicity is a sufficient condition for (PI).

According to Theorem 3.5, by the notion of synchronicity, it is possible to extend (PI) beyond a cone $C$ if only (PI) holds for vectors in $C$.

Proposition 3.7. Let $C \subset V$ be a convex cone with $C=P C+V_{2}, P C \neq\{0\}$ and let $G$ be a subgroup of $G_{P}$ with property (3.16).

The following statements are equivalent.
i) (PI) holds for $y, z \in C$
ii) (PI) holds for the vectors $y$ and $z$ which are $G$-synchronous w.r.t. $C$.

Proof. i) $\Rightarrow$ ii). Assume $y$ and $z$ are $G$-synchronous w.r.t. $C$. There exists $g \in G$ with $g y, g z \in C$. Since i), (PI) holds for $g y, g z$. By Theorem 3.5 we conclude that (PI) holds for $y$ and $z$.

The converse implication is evident because $y, z \in C$ are of course $G$-synchronous.

Now, we are able to give an equivalent condition for $G$-synchronicity. Simultaneously, the condition is sufficient for synchronicity w.r.t. $D+V_{2}$.

Proposition 3.8. Let $G$ be the group defined by (3.8) and let $D$ be the cone defined by (3.6).

The vectors $y, z \in V$ are $G$-synchronous w.r.t. $D+V_{2}$ if and only if

$$
\left\langle y, f_{\nu}\right\rangle\left\langle z, f_{\nu}\right\rangle \geq 0, \quad \forall_{\nu}
$$

Proof. If $y, z$ are $G$-synchronous, then there exists a $\xi$ such that $g_{\xi} y, g_{\xi} z \in D+V_{2}$. Hence $\xi_{\nu}\left\langle y, f_{\nu}\right\rangle \geq 0$ and $\xi_{\nu}\left\langle z, f_{\nu}\right\rangle \geq 0$ for all $\nu$. Multiplying the above inequalities side by side we obtain $0 \leq \xi_{\nu}^{2}\left\langle y, f_{\nu}\right\rangle\left\langle z, f_{\nu}\right\rangle=\left\langle y, f_{\nu}\right\rangle\left\langle z, f_{\nu}\right\rangle$ for every $\nu$.

Conversely, suppose that $\left\langle y, f_{\nu}\right\rangle\left\langle z, f_{\nu}\right\rangle \geq 0$ for every $\nu$. In this situation, the sequences defined for $y$ and $z$ by (3.14) are equal. Hence $y$ and $z$ are $G$-synchronous by (3.15).

Summarizing the above considerations we give sufficient and necessary conditions for (PI) to hold.

Theorem 3.9. Let $\left\{f_{\nu}\right\}$ be an orthogonal basis of $V_{1}$. Set $C=D+V_{2}$, where $D$ is defined by (3.6). The following statements are equivalent.
i) $y$ and $z$ are synchronous w.r.t. $C$
ii) (PI) holds for $y$ and $z$.

In particular, if

$$
\begin{equation*}
\left\langle y, g_{0} f_{\nu}\right\rangle\left\langle z, g_{0} f_{\nu}\right\rangle \geq 0, \quad \forall \nu \tag{3.18}
\end{equation*}
$$

then (PI) holds, where $g_{0} \in G_{P}$ is fixed.
Proof. The first part, i) $\Rightarrow$ ii). It is a consequence of Corollary 3.6 and Proposition 3.7.

Conversely, if ii), then $\langle P y, P z\rangle \geq 0$. Firstly, suppose that $P z=\alpha P y$. Clearly, $\alpha \geq 0$. By (3.16), which holds for $G_{P}$ and $C$, there exists a $g \in G_{P}$ such that $g y \in C$. Hence $P g y \in P C=D$. By (3.4), $g P y \in D$. Since $\alpha \geq 0, \alpha g P y \in D$. Since $z-P z \in V_{2}, g(z-P z) \in V_{2}$, because $g V_{2}=V_{2}$. Hence

$$
g z=g P z+g(z-P z)=\alpha g P y+g(z-P z) \in C .
$$

Therefore $g y, g z \in C$, i.e. $y$ and $z$ are synchronous.

Chebyshev Inequalities and Self-Dual Cones

Next, assume that $P y$ and $P z$ are linearly independent. Let us construct an orthogonal basis $\left\{e_{\nu}\right\}$ of $V_{1}$ with

$$
e_{1}=P y, \quad e_{2}=P z-\frac{\langle P z, P y\rangle}{\|P y\|^{2}} P y
$$

and let $g \in G_{P}$ be defined by (3.17). There is no difficulty to showing that

$$
\begin{gathered}
g y=\underbrace{y-P y}_{\in V_{2}}+\underbrace{\frac{\|P y\|}{\left\|f_{1}\right\|} f_{1}}_{\in D} \in C, \\
g z=\underbrace{z-P z}_{\in V_{2}}+\underbrace{\frac{\langle z, P y\rangle}{\left\|e_{1}\right\|\left\|f_{1}\right\|}}_{\underbrace{\geq 0, \text { by }(\mathrm{PI})}_{\in D}} f_{1}+\underbrace{\frac{\|P z\|^{2}\|P y\|^{2}-\langle P z, P y\rangle^{2}}{\|P y\|^{2}\left\|e_{2}\right\|\left\|f_{2}\right\|}}_{\geq 0, \text { by Cauchy-Schwarz ineq. }} f_{2} \in C .
\end{gathered}
$$

Therefore, $y$ and $z$ are synchronous as required.
Now, let us note that (3.18) is equivalent to

$$
\left\langle g_{0}^{*} y, f_{\nu}\right\rangle\left\langle g_{0}^{*} z, f_{\nu}\right\rangle \geq 0, \quad \forall \nu .
$$

By Proposition 3.8, $g_{0}^{*} y$ and $g_{0}^{*} z$ are $G$-synchronous w.r.t. $C$. Hence there exists a $g \in G$ such that $g g_{0}^{*} y, g g_{0}^{*} \in C$. Since $g g_{0}^{*} \in G_{P}, y$ and $z$ are synchronous w.r.t. $C$. For this reason (PI) holds, by the first part of this proposition. The proof is complete.

## 4. Applications to the Chebyshev Sum Inequality

Throughout this section, $V=\mathbb{R}^{n}$ with the standard inner product $\langle\cdot, \cdot\rangle$. Let $\left\{s_{i}\right\}$ be the basis of $\mathbb{R}^{n}$, where $s_{i}=(\underbrace{1, \ldots, 1}_{i}, 0, \ldots, 0), i=1, \ldots, n$. The symbols $V_{1}$ and $V_{2}$ stand for the subspace orthogonal to $s_{n}$ and its orthogonal complement, respectively, i.e.

$$
V_{1}=\left\{\left(x_{1}, \ldots, x_{n}\right): \sum_{i} x_{i}=0\right\}, \quad V_{2}=\operatorname{span}\left\{s_{n}\right\}
$$

Chebyshev Inequalities and Self-Dual Cones
Zdzisław Otachel
vol. 10, iss. 2, art. 54, 2009
Let $P$ be the orthoprojector onto $V_{1}$, i.e. $P=\mathrm{id}-\frac{\left\langle, s_{n}\right\rangle}{n} s_{n}$. In this situation, by Example 3.2, (PI) becomes the Chebyshev sum inequality (CHSI).

It is known that the convex cone of nonincreasing vectors

$$
C=\left\{x=\left(x_{1}, \ldots, x_{n}\right): x_{1} \geq x_{2} \geq \cdots \geq x_{n}\right\}
$$

is generated by $\left\{s_{1}, \ldots, s_{n},-s_{n}\right\}$. On the other side,

$$
\{(1,-1,0, \ldots, 0),(0,1,-1,0, \ldots, 0),(0, \ldots, 0,1,-1)\}
$$

is a generator of

$$
\text { dual } C=\left\{x=\left(x_{1}, \ldots, x_{n}\right): \sum_{i=1}^{n} x_{i}=0, \sum_{i=1}^{k} x_{i} \geq 0, k=1, \ldots, n-1\right\}
$$

Set $e_{i}=n P s_{i}, i=1, \ldots, n-1$. Clearly,

$$
\begin{equation*}
e_{i}=n s_{i}-i s_{n}=(\underbrace{n-i, \ldots, n-i}_{i}, \underbrace{-i, \ldots,-i}_{n-i}), \quad i=1, \ldots, n-1 \tag{4.1}
\end{equation*}
$$

## Write

$$
D=\operatorname{cone}\left\{e_{i}\right\}
$$

Clearly, $P C=D$ and $V_{2} \subset C$. Hence by (3.1),

$$
C=D+V_{2}
$$

Applying Proposition 3.2, we conclude that (PI) holds for $y, z \in\left(D+V_{2}\right) \cap$ dual $D=$ $C \cap$ dual $D$. With the aid of generators we can check that $D \subset$ dual $C$. Hence $C=$ dual dual $C \subset$ dual $D$.

By the above considerations, for arbitrary $y, z \in C$, the inequality (CHSI) holds. This is a classic Chebyshev result.

The system $\left\{e_{i}, i=1, \ldots, n-1\right\}$ constitutes a basis of $V_{1}$. Observe that

$$
\left\langle e_{i}, e_{j}\right\rangle=i(n-j) n, \quad i \leq j, i, j=1, \ldots, n-1
$$

Hence, easy computations lead to

$$
\left\langle e_{k+1}-\frac{n-k-1}{n-k} e_{k}, e_{i}\right\rangle=0, \quad i=1, \ldots, k ; k=1, \ldots, n-2 .
$$

From this, the Gram-Schmidt orthogonalization gives the orthogonal system $\left\{q_{i}\right\}$ for the basis $\left\{e_{i}\right\}$ as follows:

$$
\left\{\begin{array}{l}
q_{1}=e_{1}  \tag{4.2}\\
q_{k+1}=\frac{n-k}{n}\left(e_{k+1}-\frac{n-k-1}{n-k} e_{k}\right), \quad k=1, \ldots, n-2 .
\end{array}\right.
$$

According to (4.1) and (4.2) we obtain the explicit form of the orthogonal basis $\left\{q_{i}\right\}$

$$
\begin{equation*}
q_{k}=(\underbrace{0, \ldots, 0}_{k-1}, n-k, \underbrace{-1, \ldots,-1}_{n-k}), \quad k=1, \ldots, n-1 \text {. } \tag{4.3}
\end{equation*}
$$

Let us denote

$$
K=\widetilde{D}+V_{2}
$$

where $\widetilde{D}$ stands for the cone $\left\{q_{k}\right\}$. The convex cone $\widetilde{D}$ is self-dual w.r.t. $V_{1}$.
According to Proposition 3.3 we can assert that (CHSI) holds for $y, z \in K$.
Let $g_{0}\left(x_{1}, \ldots, x_{n}\right)=\left(-x_{n}, \ldots,-x_{1}\right)$. Clearly, $g_{0} \in G_{P}$. By Remark 1, (CHSI) holds for $y, z \in g_{0} K$. Have:

$$
g_{0} K=g_{0}\left(\widetilde{D}+V_{2}\right)=g_{0} \widetilde{D}+V_{2}=\operatorname{cone}\left\{g_{0} q_{k}\right\}+V_{2}
$$

Define $f_{k}=g_{0} q_{n-k}, k=1, \ldots, n-1$. Since $g_{0} \in G_{P}, g_{0}$ is unitary and $g_{0} V_{1}=V_{1}$, by (3.3). Hence, $\left\{f_{k}\right\}$ is an orthogonal basis of $V_{1}$. Observe

$$
\begin{equation*}
f_{k}=(\underbrace{1, \ldots, 1}_{k},-k, 0, \ldots, 0), \quad k=1, \ldots, n-1 . \tag{4.4}
\end{equation*}
$$

Write

$$
M=\operatorname{cone}\left\{f_{k}\right\}+V_{2}
$$

By Remark 1, it is evident that (CHSI) holds for $y, z \in M$.
Proposition 4.1. For $x=\left(x_{1}, \ldots, x_{n}\right) \in \mathbb{R}^{n}$

$$
\begin{aligned}
& x \in K \Longleftrightarrow \text { the sequence }\left\{\frac{1}{n-k+1} \sum_{i=k}^{n} x_{i}\right\}_{k=1}^{n} \text { is nonincreasing, } \\
& x \in M \Longleftrightarrow \text { the sequence }\left\{\frac{1}{k} \sum_{i=1}^{k} x_{i}\right\}_{k=1}^{n} \text { is nonincreasing. }
\end{aligned}
$$

Proof. We prove only the first equivalence. The second one uses a similar procedure.

Chebyshev Inequalities and Self-Dual Cones
Zdzisław Otachel

journal of inequalities in pure and applied mathematics
issn: 1443-575b

By (3.2), $K=$ dual $\widetilde{D}$, because $\widetilde{D}$ is self-dual w.r.t. $V_{1}$. Hence by (4.3) we can assert that $x \in K$ is equivalent to

$$
(n-k) x_{k} \geq \sum_{i=k+1}^{n} x_{i}, \quad k=1, \ldots, n-1 .
$$

Adding to both of sides $(n-k) \sum_{i=k+1}^{n} x_{i}$ and dividing by $(n-k)(n-k+1)$, we obtain

$$
\frac{1}{n-k+1}\left(\sum_{i=k}^{n} x_{i}\right) \geq \frac{1}{n-k}\left(\sum_{i=k+1}^{n} x_{i}\right), \quad k=1, \ldots, n-1
$$

This is equivalent to our claim.
By the above proposition, we can see that $C \subset K$ and $C \subset M$. The cone $M$ is said to be a cone of vectors nonincreasing in mean. It is easily seen that (CHSI) holds for $y, z \in-K$ and for $y, z \in-M$ (for e.g., by taking $C=K, M$ and substituting - id into $g_{0}$ in Remark 1). The statement that (CHSI) holds for vectors monotonic in mean is due to Biernacki, see [1].

The remainder of this section will be devoted to (CHSI) for synchronous vectors. We will consider relations between synchronicity and similar ordering.

Here $G_{P}$ is the group of all orthogonal matrices such that the sum of the entries of each row and column is equal to 1 or -1 . The group of all $n \times n$ permutation matrices is a subgroup of $G_{P}$, which together with the cone $C$ fulfil (3.16). The permutation group synchronicity w.r.t. $C$ is simply the relation "to be similarly ordered". It implies synchronicity w.r.t. every cone which contains $C$, e.g. $M$ or $K$.

The two vectors $x=\left(x_{1}, \ldots, x_{n}\right), y=\left(y_{1}, \ldots, y_{n}\right) \in \mathbb{R}^{n}$ are said to be similarly ordered if

$$
\begin{equation*}
\left(x_{i}-x_{j}\right)\left(y_{i}-y_{j}\right) \geq 0, \quad \forall_{i, j} \tag{4.5}
\end{equation*}
$$

The assertion that (CHSI) holds for similarly ordered vectors is a consequence of Proposition 3.7.

Theorem 3.9 states that (CHSI) is equivalent to synchronicity w.r.t. cone $\left\{f_{k}\right\}+V_{2}$ where $\left\{f_{k}\right\}$ is an arbitrarily chosen orthogonal basis of $V_{1}$. Moreover, $G$-synchronicity gives (CHSI), where $G$ is the group (3.8) acting on $\mathbb{R}^{n}$. For this reason, the specification of Theorem 3.9 can be as follows.

Let $\left\{f_{k}\right\}$ be defined by (4.4) and $G$ by (3.8) in compliance with the basis.
Corollary 4.2. (CHSI) holds for $y, z$ if and only if $y$ and $z$ are synchronous w.r.t. M.

In particular, (CHSI) is satisfied by $y$ and $z$ such that

$$
\left\langle y, U f_{k}\right\rangle\left\langle z, U f_{k}\right\rangle \geq 0, \quad k=1, \ldots, n-1,
$$

where $U$ is a fixed unitary operation with $U s_{n}=s_{n}$ or $U s_{n}=-s_{n}$, i.e. $U$ is represented by an orthogonal matrix whose rows and columns sum up to 1 or to -1 .

By Proposition 3.8 we have:
Remark 3. The vectors $y=\left(y_{1}, \ldots, y_{n}\right)$ and $z=\left(z_{1}, \ldots, z_{n}\right)$ are $G$-synchronous w.r.t. $M$ if and only if

$$
\left[\sum_{i=1}^{k} y_{i}-k y_{k+1}\right]\left[\sum_{i=1}^{k} z_{i}-k z_{k+1}\right] \geq 0, \quad k=1, \ldots, n-1
$$

Relations of similar ordering and $G$-synchronicity w.r.t. $M$ are not comparable, i.e. there exist similarly ordered vectors which are not synchronous and there exist synchronous vectors that are not similarly ordered. On the other hand, both relations imply synchronicity w.r.t. $M$ and as a consequence, (CHSI) holds.
Example 4.1. Consider $\mathbb{R}^{n}, n>3$.

For $0<\alpha<1<\beta<n-1$ set $y=(0, \ldots, 0,1-n,-\alpha), z=(0, \ldots, 0,1-$ $n,-\beta$ ). According to (4.5) and Remark 3 the vectors $y$ and $z$ are similarly ordered and are not $G$-synchronous, but they are synchronous w.r.t. $M$, so (CHSI) holds.

Now, set $y^{\prime}=f_{1}+f_{2}, z^{\prime}=f_{2}+f_{3}$, where $f_{i}$ are defined by (4.4). The vectors $y^{\prime}$ and $z^{\prime}$ are $G$-synchronous w.r.t. $M$, because $y^{\prime}, z^{\prime} \in M$, so (CHSI) holds.

On the other hand $y^{\prime}=(2,0,-2,0, \ldots, 0), z^{\prime}=(2,2,-1,-3,0, \ldots, 0)$ are not similarly ordered by (4.5), because $\left(y_{3}^{\prime}-y_{4}^{\prime}\right)\left(z_{3}^{\prime}-z_{4}^{\prime}\right)=-2(-1+3)<0$.

## 5. Applications to the Chebyshev Integral Inequality

Set $V=L^{2}$ as in Example 3.2. The characteristic function of the measurable set $A \subset[0,1]$ is denoted by $I_{A}$. Additionally we will write $e_{s}=I_{[0, s]}, 0 \leq s \leq 1$. The symbol $V_{1}$ stands for the subspace orthogonal to $V_{2}=\operatorname{span}\left\{e_{1}\right\}$, i.e. $V_{1}=$ $\left\{x \in L^{2}: \int x d \mu=0\right\}$. By Example 3.2, it is known that for the orthoprojector $P$ onto $V_{1}$ (PI) transforms into the Chebyshev integral inequality (CHII). Let $C \subset L^{2}$ be the closed convex cone of all nonincreasing $\mu$ a.e. functions. It is known (see [5, Theorem 3.1 and 3.3]) that:

$$
\begin{align*}
C & =\operatorname{cone}\left(\left\{e_{s}: 0 \leq s \leq 1\right\} \cup\left\{-e_{1}\right\}\right)  \tag{5.1}\\
\text { dual } C & =\operatorname{cone}\left\{I_{\Pi}-I_{\Pi+\varepsilon}: \varepsilon>0, \Pi, \Pi+\varepsilon \subset[0,1]\right\}
\end{align*}
$$

where $\Pi$ stands for an interval.
The Haar system:

$$
\begin{align*}
\chi_{0}^{0} & =e_{1}  \tag{5.2}\\
\chi_{n}^{k}(t) & = \begin{cases}2^{n / 2}, & \frac{2 k-2}{2^{n+1}} \leq t<\frac{2 k-1}{2^{n+1}} \\
-2^{n / 2}, & \frac{2 k-1}{2^{n+1}} \leq t<\frac{2 k}{2^{n+1}} \\
0, & \text { otherwise }\end{cases} \\
n & =0,1, \ldots, \quad k=1,2, \ldots, 2^{n}
\end{align*}
$$

forms an orthonormal basis of $L^{2}$. In particular, $\mathcal{H}=\left\{\chi_{n}^{k}: n=0,1, \ldots, k=\right.$ $\left.1, \ldots, 2^{n}\right\}$ is an orthonormal basis of $V_{1}$.

Let

$$
D=\text { cone } \mathcal{H}
$$

issn: 1443-575b

The cone $D$ is self-dual w.r.t. $V_{1}$, so by (3.2) we have:

$$
\begin{equation*}
\text { dual } D=D+V_{2} \text {. } \tag{5.3}
\end{equation*}
$$

By (5.1), observe that $\mathcal{H} \subset$ dual $C$, hence $C=$ dual dual $C \subset$ dual $\mathcal{H}=$ dual $D$. Combining this with (5.3), we obtain

$$
\begin{equation*}
C \subset D+V_{2} \tag{5.4}
\end{equation*}
$$

From (5.4) and Corollary 3.6 it follows that
Corollary 5.1. (CHII) holds for $y, z \in D+V_{2}$.
The cone $D+V_{2}$ contains the cone of all nonincreasing $\mu$ a.e.functions in $L^{2}$.
It is easily seen that the cone $D+V_{2}$ contains functions which are not nonincreasing $\mu$ a.e.

Let $G$ be the group (3.8) acting on $L^{2}$ with the Haar system. Employing the $G$-synchronicity relation w.r.t. $D+V_{2}$, by Theorem 3.9 we get:

Corollary 5.2. (CHII) holds for $y, z \in L^{2}$ if only

$$
\begin{equation*}
\langle y, \chi\rangle\langle z, \chi\rangle \geq 0, \quad \forall \chi \in \mathcal{H} . \tag{5.5}
\end{equation*}
$$

We next discuss the relation between the condition (5.5) and the known sufficient conditions for (CHII). One of these is the condition that $y$ and $z$ are similarly ordered, i.e.

$$
\begin{equation*}
[y(s)-y(t)][z(s)-z(t)]] \geq 0, \quad \text { for all } 0 \leq s, t \leq 1 \tag{5.6}
\end{equation*}
$$

(see e.g. [6, pp. 198-199]). Now, we show by an example that the $G$-synchronicity condition (5.5) is not stronger than the condition of similar ordering (5.6) in $L^{2}$.

Chebyshev Inequalities and Self-Dual Cones

Example 5.1. In $L^{2}$ let $y=\chi_{2}^{1}+\chi_{2}^{2}, z=\chi_{2}^{2}+\chi_{2}^{3}$, where $\chi_{i}^{j}$ are defined by (5.2). The vectors $y$ and $z$ are $G$-synchronous w.r.t. $D+V_{2}$, because they are in $D$.

On the other hand

$$
\begin{array}{lll}
y(s)=2, & 0 \leq s \leq \frac{1}{8} \\
y(t)=0, & \frac{4}{8} \leq t \leq \frac{5}{8}, & z(t)=2,
\end{array} \quad \frac{0}{8} \leq t \leq \frac{4}{8} \frac{5}{8}
$$

From this, $[y(s)-y(t)][z(s)-z(t)]]=[2-0][0-2] \leq 0$ for any $0 \leq s \leq \frac{1}{8}$ and $\frac{4}{8} \leq t \leq \frac{5}{8}$. Thus $y$ and $z$ are not similarly ordered.

Now, we recall that a function $y \in L^{2}$ is nonincreasing (nondecreasing, monotone) in mean if the function $s \mapsto \frac{1}{s} \int_{0}^{s} y d \mu$, is nonincreasing (nondecreasing, monotone).

Differentiating $\frac{1}{s} \int_{0}^{s} y d \mu$ we can easy obtain that $y$ is nonincreasing in mean if and only if $\frac{1}{s} \int_{0}^{s} y d \mu \geq y(s), \mu$ a.e.

It is known that (CHII) holds for $y$ and $z$ which are monotone in mean in the same direction (see [1], cf. also [6, pp. 198-199]). Johnson in [2] gave a more general condition. Namely, if

$$
\begin{equation*}
\left[\frac{1}{s} \int_{0}^{s} y d \mu-y(s)\right]\left[\frac{1}{s} \int_{0}^{s} z d \mu-z(s)\right] \geq 0, \quad \forall_{0<s<1} \tag{5.7}
\end{equation*}
$$

then (CHII) holds for $y$ and $z$.

## Remark 4.

1. There exist functions in cone $\mathcal{H}$ which are not nonincreasing in mean.
2. There exist functions nonincreasing in mean which are not in cone $\mathcal{H}$.
3. There exist functions in cone $\mathcal{H}$ for which (5.7) does not hold, i.e. the condition (5.5) is not stronger than (5.7).

## Proof. An easy verification shows that:

Ad. 1) $\chi_{n}^{k} \in \mathcal{H}, k>1$ are not nonincreasing in mean.
Ad. 2) Set $f=I_{[0,1 / 2)}-2 I_{[1 / 2,3 / 4)} . f$ is nonincreasing in mean and is not in cone $\mathcal{H}$ because $\left\langle f, \chi_{1}^{2}\right\rangle<0$.

Ad. 3) Set $y=\chi_{1}^{2}, z=\chi_{2}^{3}$. For $\frac{5}{8}<s<\frac{6}{8}$ have:

$$
\left[\frac{1}{s} \int_{0}^{s} y d \mu-y(s)\right]\left[\frac{1}{s} \int_{0}^{s} z d \mu-z(s)\right]=-\frac{\sqrt{2} / 2}{s} \cdot \frac{3 / 2}{s}<0
$$

Chebyshev Inequalities and Self-Dual Cones
Zdzisław Otachel
vol. 10, iss. 2, art. 54, 2009
The set of all $L^{2}$-functions nonincreasing in mean constitutes a convex cone. It will be denoted by $M$. Let $\mathcal{M}_{0}$ be the class of all step functions of the form

$$
g_{s, t}=I_{[0, s)}-\frac{s}{t-s} I_{[s, t]}, \quad 0<s<t<1
$$

## Proposition 5.3.

$$
\begin{aligned}
M & =\operatorname{dual} \mathcal{M}_{0} \\
P M & =\operatorname{dual}_{V_{1}} \mathcal{M}_{0}=\operatorname{cone} \mathcal{M}_{0} \\
M & =\operatorname{cone} \mathcal{M}_{0}+V_{2}
\end{aligned}
$$

Proof. By definition, $f \in M$ if and only if

$$
\frac{1}{s} \int_{0}^{s} f d \mu \geq \frac{1}{t} \int_{0}^{t} f d \mu \quad \text { for all } 0<s<t<1
$$

After equivalent transformations we obtain

$$
\int_{0}^{s} f d \mu \geq \frac{s}{t-s} \int_{s}^{t} f d \mu \quad \text { for all } 0<s<t<1
$$

This is simply $f \in$ dual $\mathcal{M}_{0}$, so the first equation holds.
To show the second equation, note that $\mathcal{M}_{0} \subset M \cap V_{1}$. Hence

$$
\operatorname{dual}\left(M \cap V_{1}\right) \subset \operatorname{dual} \mathcal{M}_{0}=M
$$

by the first equation. It follows that $V_{1} \cap \operatorname{dual}\left(M \cap V_{1}\right) \subset M \cap V_{1}$, i.e.

$$
\begin{equation*}
\operatorname{dual}_{V_{1}}\left(M \cap V_{1}\right) \subset M \cap V_{1} . \tag{5.8}
\end{equation*}
$$

Fix $f \in M \cap V_{1}$ and let $g \in M \cap V_{1}$ be arbitrary. For such $f$ and $g$ (CHII) holds and takes the form:

$$
\int_{0}^{1} f g d \mu \geq \int_{0}^{1} f d \mu \cdot \int_{0}^{1} g d \mu=0 \cdot 0=0
$$

i.e. $f \in$ dual $_{V_{1}}\left(M \cap V_{1}\right)$. Therefore

$$
\begin{equation*}
M \cap V_{1} \subset \operatorname{dual}_{V_{1}}\left(M \cap V_{1}\right) . \tag{5.9}
\end{equation*}
$$

Since $M=$ dual $\mathcal{M}_{0}$, dual $M=$ cone $\mathcal{M}_{0}$. Now, observe that $V_{2} \subset M$. This implies by (3.1) that $M=P M+V_{2}$. Furthermore, in this situation $P M=M \cap V_{1}$. The above gives

$$
\begin{aligned}
\operatorname{dual} M & =\operatorname{dual}\left(M \cap V_{1}+V_{2}\right) \\
& =V_{1} \cap \operatorname{dual}\left(M \cap V_{1}\right)=\operatorname{dual}_{V_{1}}\left(M \cap V_{1}\right) .
\end{aligned}
$$

Hence

$$
\begin{equation*}
\operatorname{dual}_{V_{1}}\left(M \cap V_{1}\right)=\operatorname{cone} \mathcal{M}_{0} . \tag{5.10}
\end{equation*}
$$

Combining (5.8), (5.9) and (5.10) we obtain the required equations. The third equation is a consequence of the second one. The proof is complete.

The second equation of the above propositions immediately gives:
Remark 5. The convex cone of all $L^{2}$-functions nonincreasing in mean with integral equal to 0 is self-dual w.r.t. $V_{1}$.

Taking $C=M$ in Theorem 3.1, by Proposition 5.3 we easily obtain:
Corollary 5.4. If $\int f d \mu \int g d \mu \leq \int f g d \mu$ holds for all functions $f \in L^{2}$ monotone in mean, then $g \in L^{2}$ is also monotone in mean.
